FOREWORD

BY K. N. CHAUDHURI

This book marks a new approach to the study of Indian economic history. The great issues in the debates among historians so far have been the effects of colonial rule in the subcontinent during the nineteenth and twentieth centuries. Economic institutions were investigated in depth mainly from the point of view of policy-makers. The actual performance of the economy, the rate of its integration, and the decomposition of the causal forces at work were questions to which only insufficient attention was paid. Dr Islam takes as his central theme of inquiry the measurement of agricultural output in Bengal during the period from 1920 to 1946. The extension of the market for agricultural crops, which was a notable feature of the agrarian economy of India in the nineteenth century, failed to produce any significant concomitant industrial-urban development. Furthermore, agriculture itself stagnated after the initial effects of market expansion had worked itself out. The absence of major industrialising efforts not only limited the produce and labour markets but also prevented innovation in crop techniques and possible changes in the institution of landholding. Dr Islam has taken these questions as his point of departure and tried to quantify the precise direction of Bengal's economy for a critical period of this century. His book is the first serious attempt on the part of a historian from South Asia to use advanced statistical methods and techniques of computer analysis to provide answers to historical problems. Dr Islam has made an exhaustive analysis of the available crop statistics for all the districts of Bengal and computed the trend rates for output, yield, and acreage. He has also thrown new light on the accuracy and reliability of the basic data. His work supplements the pioneer study undertaken by George Blyn many years ago in the pre-computer age and it adds a new insight into the subject. When Dr Islam began his research as a post-graduate student his training was that of a historian. It is a considerable achievement on his part to have ventured out into a new methodological area and successfully mastered its technical details.

K. N. CHAUDHURI

Studies, University of London*

PREFACE

The present work attempts a detailed study of the historical experience in the agricultural sector in undivided Bengal during the period 1920/21 to 1945/46. The book is divided into two parts. The first part is devoted to an examination of the quality of the officially published crop statistics and the analysis of the trends in crop output, acreage under cultivation and yield per acre. The second part deals with the most important factors which directly or indirectly influenced the trends in agricultural production, viz. impact of price, physical capital assets, credit and the role of the landlords.

The research which finally led to this study was begun in 1968 and an earlier version of this book was presented for the degree of PhD in the University of London in 1972. During these years of work on this book I have incurred a long list of obligations. None are greater than those I owe to Dr K. N. Chaudhuri who supervised my research and the writing of the dissertation. I am most grateful to him for the many hours of careful attention he gave, for the unrestrained development of thought which he encouraged and for his useful criticisms and advice. I am also grateful to him for writing the 'Foreword'. The preparation of the revised manuscript was started when I was working with Prof. Dietmar Rothermund at the South Asia Institute of Heidelberg University. I am grateful to him for his valuable suggestions. I am also indebted to Mr B. H. Farmer, Director, Centre of South Asian Studies, University of Cambridge, who took keen interest in the publication of this book.

I benefitted from the stimulating discussions I had with Dr John Hurd II (University of Oakland, USA), Dr M. D. Morris (University of Washington), Dr Biplab Das Gupta (University of Sussex), Michael Hodd and T. J. Byres (School of Oriental and African Studies, University of London) and Prof. A. Razzaque (University of Dacca). Miss J. Skegg and Mrs J. A. Lallor helped me in processing the huge volume of statistical data. I would like to record my gratitude to all of them. Others who helped me in different ways include Dr A. M. Chaudhury, Dr Sirajul Islam, P. N. Chaudhuri, Akhter Hussain, Dr S. Ghatak, Dr S. K. Dey, B. R. Khan, Ahmed Kamal, Sushil Ranjan Howlader, Fariduddin Ahmed, Mizanur Rahman, A. Salam, Hedayet Hussain and Tajul Islam Hashmi. I offer my sincere thanks to all of them.

Preface

My thanks are also due to Faruk Chaudhuri and Nurul Islam for their secretarial assistance, and to Muntasir Mamun and Hossain Shahid Faroqui for their help in proof-reading.

I must also extend my thanks to the Syndics of the Cambridge University Press for undertaking the publication of this book. My thanks are also due to all the members of the staff who worked on the design and production of this book, and especially to Mr Francis Brooke who saved me from numerous errors by his persistent questioning and patient sub-editing of the manuscript.

I am grateful to the authorities of the University of Chittagong for granting me study leave for the period of research. I also gratefully acknowledge the financial assistance I received from the School of Oriental and African Studies and the Central Research Fund, University of London. The financial help from the Central Research Fund enabled me to obtain some essential research materials from Calcutta.

For my research materials I depended on the following libraries: The British Museum Library, the India House Library, the India Office Library and Records, the Library of the London School of Economics, the National Library of India (Calcutta), the Library of the School of Oriental and African Studies, the Senate House Library, Dacca University Library and the Library of the Bangladesh Institute of Development Studies. I am grateful to the Librarians and other members of the staff of these Libraries. My thanks are also due to the members of staff of the University of London Computer Centre and the Computer Department of the University College, London.

Finally my thanks are due to Nahar, my wife, for all her encouragement and assistance. All errors of logic and facts are, however, entirely my own.

M.M.I.

INTRODUCTION

The establishment of British rule in India led to a great expansion of the external demand for her agricultural raw materials. Whereas in the preceding centuries production for domestic consumption and transactions in kind had been the dominant pattern, under the changed circumstances in the nineteenth century agriculture became much more market oriented. In other words, growing emphasis began to be put on the production and marketing of certain crops which were needed for export on the world market. Working in the same direction was the influence of the growth of commercial centres and the development of certain industries. The net result was that the surplus productive capacity in agriculture, which had for so long been locked up as a result of the small size of market, now came to be increasingly utilised.

Among the regions of India where the impact of the widening of the market was felt, Bengal occupied an important position. The effect of the widening market was naturally concentrated most in the agricultural sector. In particular, foreign demand for raw jute and the development of the jute industry in and around Calcutta stimulated the production of this crop.¹ The impetus which was thus given by the establishment of wider commercial contact with the outside world led to a remarkable expansion of agriculture but it seems that by 1920 the possibilities for the further expansion of cultivation had become limited. An important development which accompanied the process of widening of the market was the gradual increase of the pressure on land along with the growth of population.² As the expansion of agriculture was not accompanied by industrial-urban development on a sufficiently large scale the man-land ratio gradually deteriorated. Thus, according to the Census of 1921 the percentage of total population directly dependent on agriculture was as high as 77.3 and cultivated land per worker was only 2.3 acres.³

¹ For details see, B. B. Chaudhuri, 'Growth of Commercial Agriculture in Bengal 1859-1885', *Indian Economic and Social History Review*, Vol. 7 (1970), pp. 25-60; 'Growth of Commercial Agriculture and its Impact on Peasant Economy', *ibid.*, pp. 211-52.

² For a discussion on the trends in the growth of population in India and their explanation see, K. Davis, *The Population of India and Pakistan* (New York, 1968), Chs. 2, 5.

³ *Census of India, 1921, Bengal* (Calcutta, 1923), p. 377. If it is believed that there was substantial 'de-industrialisation' in India during the British rule, this would mean that the increase in the number of people engaged in agriculture was not only in absolute but also in

The present study is an attempt to examine the performance of the agricultural sector in such an environment. We are directly concerned with a period which is much later than the time when market forces began penetrating rural areas. However, in order to place the present study in its proper perspective it is necessary that an attempt be made to review the process by which this environment was created, the theoretical justifications which were put forward by the classical economists and the policy implications which the British imperial government derived from such reasonings. This will show that the assumptions of the nineteenth-century economists and administrators, which were generally very different from the thinking of present-day economists who advocate growth, were largely responsible for the creation of conditions of stagnation rather than self-sustained economic development.

CLASSICAL AND CONTEMPORARY VIEWS OF DEVELOPMENT

On the basis of their strategy for the economic development of the under-developed countries the present day advocates of growth may be broadly divided into two groups. One group believes that the economic life of the under-developed countries could be transformed by giving industrialisation top priority. The second group recommend that the development of the two sectors of the economy – agriculture and industry – should proceed simultaneously.¹

The thinking of the classical economists was in sharp contrast to the opinions of contemporary development economists, particularly those belonging to the first group. They advocated economic development through the international division of labour, and recommended that the underdeveloped countries should specialise in the production of primary products for which they were suitable, and the exports from which could finance the imports of manufactured goods from abroad. It was believed that this strategy would transmit economic growth to all parts of the world. Thus, Adam Smith, the most prominent advocate of such a model of economic develop-

proportional terms. For a discussion of this problem on the basis of Census data see, Daniel and Alice Thorner, *Land and Labour in India*, (Bombay, 1962).

¹ The various assumptions of the economists in the first group are discussed by R. M. Hartwell, *The Industrial Revolution and Economic Growth* (London, 1971), Ch. x; H. Myint, *The Economics of the Developing Countries* (London, 1964), Ch. vii; Concurrent Growth of agriculture and industry is advocated by, among others, W. A. Lewis, *The Theory of Economic Growth* (London, 1955), pp. 276–83; R. Nurkse, 'The Conflict between "Balanced Growth" and International Specialisation' in *Lectures on Economic Development* (Istanbul, 1958); H. Gaskell, 'Importance of Agriculture in Economic Development' in W. W. Mcpherson (ed.), *Economic Development of Tropical Agriculture* (University of Florida Press, 1968).

Introduction

ment, contended that international trade would overcome the small size of the domestic market and create an effective demand for primary products. This has been called the 'vent for surplus' theory. Another feature of this school of thought is its belief that, by widening the extent of the market, international trade would lead to the division of labour and raise general productivity. This would improve human skill, encourage technical innovations and thereby would provide a satisfactory basis for continuous economic development.¹

Although the dynamic aspect of international trade did not occupy a central place in the writings of other classical or neoclassical economists there was nonetheless some recognition of the growth-transmitting aspect of trade above and beyond the static gains from comparative advantage. In this interpretation gains from trade were entirely consistent with the gains from growth. Indeed, the latter could be expected to increase *pari passu* with the extension of foreign trade. J. S. Mill was exceptionally clear on this point. Trade, according to comparative advantage, results in a 'more efficient employment of the productive resources of the world', and this may be considered the 'direct economical advantage of foreign trade. But', he emphasises, 'there are, besides, indirect effects which must be counted as benefits of a high order.' One of the most significant of these 'indirect' benefits is 'the tendency of every extension of the market to improve the process of production. A country which produces for a larger market than its own, can introduce a more extended division of labour, can make greater use of machinery and is more likely to make inventions and improvement in the process of production.'²

THE INFLUENCE OF POLITICAL ECONOMY

Further, once such a dynamic role was assigned to international specialisation it did not remain confined to political economists but became the 'confirmed conviction'³ of the rising class of merchants, traders, manufacturers and their representatives in the British Parliament. It was contended that since international specialisation was so beneficial in raising productivity and transmitting economic growth the government should go beyond the negative policy of removing all obstacles to commercial intercourse and

¹ This part of the discussion is based on the article by H. Myint, 'The "Classical Theory" of International Trade and Underdeveloped Countries', *Economic Journal*, Vol. 68 (1958), reprinted in I. Livingstone (ed.), *Economic Policy for Development* (London, 1971), pp. 85–112.

² Cited by G. M. Meier, *The International Economics of Development: Theory and Policy* (Tokyo, 1968), pp. 217–18. The names of other classical economists who shared this view are mentioned in this book.

³ F. F. Clairmonte, *Economic Liberalism and Underdevelopment* (Bombay, 1960), p. 16.

initiate a positive policy of facilitating increased production and export of primary goods. Under such an impulse the foreign rulers of India pursued what may be called a policy of selective intervention. In other words, while the government maintained a policy of non-intervention in some areas, for example denial of tariff protection to indigenous industries, non-interference in foodgrain movements under conditions of recurring famines, unwillingness to play a positive role in industrial development, in some other areas it went far beyond strict *laissez-faire* policy, for example in subsidising or guaranteeing private investments, altering land regulations to aid investment in plantations and providing incentives for the production of agricultural raw materials through irrigation and investment in infrastructure, including transport facilities¹ for raw materials export.

Thus, the notion of complementary development within the empire and the stress on India's comparative advantage in the production of agricultural raw materials (as against England's advantage in the production of industrial goods) led the new generations of administrators, merchants and manufacturers to argue that the government should do all in its power to help India perform her special role as the supplier of raw materials. The conventional wisdom came to be that to stimulate the production and export of raw materials 'was the best means of improving [India's] internal resources' (Wilson), 'agriculture must be her staple industry' (Trevelyan). The exchange of manufacturers from Europe 'for those raw staples in the production of which this country has special advantage' (Bengal chamber of commerce) was the ideal division of labour between the colony and the metropolitan country.²

ECONOMIC DEVELOPMENT

There have always been dissenters from this optimistic view of economic development by backward countries through specialisation in the production of agricultural raw materials. With the present concern for the under-

¹ Route mileage of railways increased from 288 in 1857 to 7322 in 1877. That the expectation of raw material supply was an important consideration behind railway investment has been shown by W. J. Macpherson, 'Investment in Indian Railways 1845–75', *Economic History Review*, Vol. viii (New Series), 1955; and Daniel Thorner, *Investment in Empire: British Railway and Steam Shipping Enterprise in India 1825–49* (Philadelphia, 1950). The impact of railways on the relative production of the different groups of crops is examined by M. B. McAlpine, 'Railroads, Cultivation Patterns and Foodgrains availability: India 1860–1900', *The Indian Economic and Social History Review*, Vol. xii, No. 1. Out of a total acreage of 197.25 millions under cultivation in 1880 the irrigated area in the country was 29.2 million acres; see, *Report on Moral and Material progress 1882–83*, p. 182.

² Cited by S. Bhattacharya, *Financial Foundations of the British Raj* (Simla, 1971), p. liv. This author has shown that State action in increasing the production and exports of agricultural raw materials was advocated by the classical economists. See pp. 17–18.

Introduction

developed countries the critics of the optimistic school are more numerous and their arguments more challenging. Several points of view have been strongly put forward. Firstly, the thesis which has been most widely discussed is the secular deterioration in the commodity terms of trade for the countries producing raw materials and the consequent transfer of income. This deterioration is attributed to the relative decrease in the demand for primary products and the relative increase in the demand for manufactured goods, diverse movements of primary product prices and industrial prices over successive business cycles, the greater number of monopoly elements in industrial markets and differences in the distribution of gains from increased productivity. With regard to the diverse movements of prices over successive business cycles it has been argued that the prices of agricultural raw materials have increased sharply during periods of boom but have subsequently lost their gains in the downswing of the trade cycle. On the other hand, though the prices of manufactured goods have risen less in prosperous years they have not fallen as far in depressions as they have risen in booms. Thus, over successive cycles the gap between the prices of the two groups of commodities has widened. The differences in the gains from increased productivity achieved through technical progress are attributed to the fact that whereas in the industrialised countries the gains from increased productivity in manufactured goods have been distributed in the form of higher wages and profits rather than lower prices, in the case of food and raw material production in the underdeveloped countries the gains in productivity, although smaller, have been distributed in the form of price reductions. Secondly, a transfer of income away from the countries specialising in the production of agricultural raw materials comes about not only through the deterioration in the terms of trade but also from the official transfer of funds ('Home charges' in the case of India), private remittances by foreign officials, dividends and interest payments by shipping and banking interests, plantations and other investors. Thirdly, there is the familiar view that since agriculture is subject to diminishing returns the expansion of primary exports will come to a stop sooner or later when suitable natural resources have been fully brought into use or are exhausted. Fourthly, outlook and institutions in the agricultural sector are generally conservative. It is rightly argued that such conservatism becomes an obstacle to rapid technical progress in the production process.¹

¹ There are, of course, differences of emphasis in the various arguments. For detailed discussion on the views of the different authors critical of the classical model see Myint, *op. cit.*, Ch. 9; Szentes, *The Political Economy of Underdevelopment* (Budapest, 1971), Ch. vi; Meier, *op. cit.*, particularly Chs. 3 and 7; W. Baer, 'The Economics of Prebisch and the ECLA', *Economic Development and Cultural Change*, Vol. 10, No. 2. Some estimates of economic drain from British India are presented by Angus Maddison, *Class Structure and Economic Growth* (London, 1971), pp. 63–70.

For all these reasons it is now generally believed that self-sustained economic development cannot be built on the expansion of primary products alone.

Industrial–urban development. A closer scrutiny, however, would suggest that far from maintaining self-sustained growth under the classical scheme, even the opportunity for the realisation of the full potential of agricultural development remains limited in a long-settled country like India. According to T. W. Schultz economic development takes place in a specific locational matrix which is primarily industrial–urban in composition. With particular reference to agriculture Schultz hypothesised that those parts of agriculture located favourably relative to the industrial–urban centre are more developed than those situated at the periphery.¹ In other words, the structural diversification of the economy through industrialisation creates a favourable environment for the transformation of the agricultural sector through its impact on the product market, as well as labour and capital markets. Industrialisation creates an expanding domestic market for the increased and diversified products of the agricultural sector. The availability of such a market is necessary in order to ensure a more remunerative price level both in the short and the long-run and thus to induce cultivators of food to make use of new technology. Then, the emerging industrial sector absorbs an increasing proportion of the available labour force. This contributes to the reorganisation of agriculture by preventing an aggravated pressure on land. Moreover, as there is a rise in the level of wages (imputed or paid) in the rural areas those who remain in agriculture are induced to find ways of raising their productivity so that they are worth these high wages. This makes it possible to increase the scale of farming and raise the capital–labour ratio. Thirdly, the increase in the capital–labour ratio is facilitated by the increase in the aggregate financial resources in the rural and urban areas. New financial institutions come into being and these cater for the needs of both the industrial and agricultural sectors.

From such an elaboration of the contributions of industrial–urban development to the transformation of the agricultural sector it should not, however, be concluded that the basic relationship between the two sectors is one of

¹ T. W. Schultz, 'Reflections on Poverty Within Agriculture', *Journal of Farm Economics*, Vol. LVIII, No. 1 (1950), pp. 1–15; *The Economic Organisation of Agriculture* (New York, 1953). This hypothesis has been substantiated by the findings of different authors. See, W. H. Nicholls, 'Industrialisation, Factor Markets, and Agricultural Development', *Journal of Political Economy*, Vol. LXIX, No. 4 (1961), pp. 319–40; A. M. Tang, *Economic Development in the Southern Piedmont, 1860–1950: Its Impact on Agriculture* (Chapel Hill, 1958); W. H. Nicholls, 'The Transformation of Agriculture in a Semi-Industrialised Country: The Case of Brazil' in Eric Thorbecke (ed.), *The Role of Agriculture in Economic Development* (New York, 1969), pp. 311–85.

Introduction

unidirectional causation from the former to the latter. In a number of ways agriculture makes a decisive contribution to industrialisation. Firstly, in the earlier periods, when industrial capital has not been accumulated, an agricultural surplus may be mobilised for the financing of industrialisation. This is suggested both by economic and historical reasoning and experience.¹ Secondly, agricultural development contributes to industrialisation by expanding the market for new products. Finally, agriculture helps industrialisation by releasing labour and providing food supplies for the expanding labour force. The problem of providing food supplies for the growing labour force has received special attention in several views of the development process.² Lewis emphasises the supply of subsistence food to industrial labour as an important capital contribution from the agricultural sector.³

From the foregoing discussion it can be argued that the basic relationship between agriculture and industry is one of mutual rather than unidirectional causation. The historical experience of the economic development of Japan clearly points to such a relationship.⁴ Similarly with regard to the place of agriculture in British economic growth it is now being argued that the relationship between the agricultural and industrial sector is not one of unidirectional causation from industry to agriculture or vice versa, but one of mutual interrelatedness. Thus, after a careful examination of the timing and progress of the two related features of agricultural development – the enclosure movement and adoption of new farm technology – Deane comes to the conclusion that the Agricultural Revolution did not precede the changes in the methods and levels of industrial production. Nor did the Industrial Revolution cause the transformation in agriculture.⁵ Changes in industry and agriculture were ultimately related in a process in which the main relationship was one of simultaneous interdependence or mutual causation.⁶ Thus, to

⁴ The sectoral interdependence in Japan is shown by Kazushi Ohkawa, ‘Concurrent Growth of Agriculture and Industry: A Study of the Japanese Case’ in R. N. Dixey (ed.), *International Explorations of Agricultural Economics* (Ames, Iowa, 1964). See, also by the same author, ‘Phases of Agricultural Development and Economic Growth’ in K. Ohkawa, B. F. Johnston and H. Kaneda (eds.), *Agriculture and Economic Growth: Japan’s Experience*, (Tokyo, 1969), Ch. 1.

⁵ P. Deane, *The First Industrial Revolution* (Cambridge, 1967), p. 43.

⁶ R. M. Hartwell, *The Causes of the Industrial Revolution in England* (London, 1967), pp. 16–17. There are two other views about the nature of the relationship between agricultural and industrial growth in England which might be mentioned. At one extreme

conclude this part of the discussion, it would appear that,

In general, the process of economic growth contains, as one of its major characteristics, the interdependence between various sectors of the economy: the growth (or retardation) of a particular sector influences, and in turn is influenced by, the growth (or retardation) of the other sectors. . . . Economic growth usually leads to an increasingly close sectoral interdependence of the economy. Agriculture and industry would follow this general trend, but with a variety of patterns from one country to another and from one phase to another within a single country.¹

In the case of a long-settled country like India the importance of the concurrent growth of the industrial and agricultural sectors assumes particular significance. Since the pressure on land was increasing, what was most needed for the transformation of agriculture was the structural diversification of the economy through industrial–urban development. But the classical scheme of economic development through specialisation in the production of agricultural raw materials hardly left any scope for large-scale industrialisation in India. Thus, the implementation of the classical scheme implied that whereas the absolute size of the labour force engaged in the agricultural sectors of countries undergoing industrial–urban development would decline or remain constant, in India the pressure of population on land would become more acute with the passage of time. This, in turn, would be crucial for agricultural development in India. This is so because emphasis on agriculture would mean that even allowing for an improvement in per capita income as a result of the initial expansion of the agricultural output, increasing population would lead to shrinking agricultural surplus and consequent lower levels of reinvestment.

In this connection another important feature of industrial–urban development may be pointed out. Economic development involves the transformation of the wider cultural matrix against which economic activities take place. Industrialisation helps achieve such a transformation to the extent that it creates an intellectual environment which is more secular in outlook and less tradition-bound.² In this respect also we see the particular importance of industrial development for a country like India. But specialisation in the production of agricultural raw materials would mean that the desired transformation of the traditional value system would not take place.

there is the view of Arthur Young and his associates that the Agricultural Revolution arose out of the needs of the Industrial Revolution. The other extreme is that increase in agricultural productivity was a 'precondition' for the Industrial Revolution. For details see, W. W. Rostow, *Stages of Economic Growth* (Cambridge, 1971).

¹ Ohkawa, *op. cit.*, p. 205. For a discussion on how lack of industrialisation can have adverse effects on agriculture see, C. Geertz, *Agricultural Involution: The Process of Ecological Change in Indonesia* (Berkeley, 1963).

Introduction

Technological development. The importance of concurrent development of the two sectors of the economy can, therefore, hardly be exaggerated in the case of a country like India. However, before we proceed it must be pointed out that though a simultaneous development of the industrial sector fulfils a necessary condition for agricultural development, this, in itself, is not sufficient. In a long-settled country the scope for the extension of cultivation to new areas is obviously more limited than in a newly-settled country. In such a situation what is needed, particularly once cultivation has extended as far as is possible, is improvement in the productivity of land already under cultivation. Up to a point this can perhaps be done by increasing the use of such traditional inputs as labour, animal power and implements for tillage and the improvement of the methods of irrigation or the pattern of crop rotation. But sooner or later a stage is reached when the gains from the increase of these inputs, with which the cultivators have long been acquainted, will be severely limited.¹ In other words, better resource allocation, more savings and investment restricted to the traditional factors of production will not be remunerative. At such a stage the necessity of obtaining additional output will require the introduction of a technology which will lead to an upward shift of the aggregate production function. Again, it is not the introduction of a once-for-all change. If agricultural development is to be sustained the techniques of production must be constantly changing. When they stop changing agriculture once more becomes stagnant.

Technological progress as defined here may be viewed as the combined effect of two processes: (a) research and experimentation and (b) diffusion. The first process includes the search for new methods and materials from other countries, testing them for their usefulness locally and perhaps modifying them. Among these methods may be mentioned experimentation to develop new strains of crops, soil treatment, disease control measures, livestock medicine and machinery, all of which make agriculture more productive. Once the new techniques are developed at the research station there arises the further necessity of popularising them among the cultivators through agricultural extension services and ensuring their regular supply in the market. For two overriding factors such research and experimentation and the popularisation of new techniques must usually be undertaken by the State. Firstly, private agencies cannot take advantage of all the benefits from increased production made possible by the development and distribution of new techniques. Secondly, there are known indivisibilities in the methods and staff of scientists required for the production of new factors. One or two

¹ The discussion on the importance of the introduction of new technology and the necessity of its development and supply by the government is based on the work by T. W. Schultz, *Transforming Traditional Agriculture* (Yale University Press, 1965).

scientists with a simple laboratory can hardly be expected to produce new agricultural factors of production suited to the conditions in a particular region. This task usually requires a large number of scientists and expensive facilities for experimental works. Similarly, in the case of agricultural extension services there are important size considerations. For these and other reasons it is clear that it is the government which should take up responsibility for research into it and the popularisation of new techniques of production.¹

Thus, given that the cultivators respond favourably to new opportunities, sustained growth in the agricultural sector depends on (a) an environment characterised by favourable product, labour and capital markets through industrial development; and (b) the availability of constantly changing technology which will require some element of state action.

The conditions for development, and the case of India. How far were these two conditions fulfilled in India or Bengal? With regard to the creation of a favourable economic environment through industrialisation it is needless to mention that by any standard India remained backward in the field of industrial development.² As mentioned earlier, this backwardness cannot wholly be attributed to the classical scheme of economic development and the policy implications drawn from it by the foreign rulers.³ However, it must be pointed out that the policy of the government with regard to industrial development in India was unfavourable, and this was of crucial significance.⁴

¹ A. M. Tang has tried to explain measured technological progress in Japanese agriculture in terms of government expenditure on agricultural research, extension and rural education by forming a regression of the former on the latter. On the basis of the goodness of fit he has claimed that more than 70% of the variation in outputs is explained. For details see his 'Research and Education in Japanese Agricultural Development, 1880–1938', *Economic Studies Quarterly*, Vol. 13 (1969), pp. 27–41 and 91–9.

² Between 1901 and 1931 the proportion of industrial workers in the total labour force hardly changed and although there was no detailed computation in 1941 the evidence available from other sources indicates that there was hardly any change over 1931. For details see Thorner, *op. cit.* For a discussion on the record of industrialisation in British India see, D. H. Buchanan, *The Development of Capitalistic Enterprise in India* (London, 1966), Chs. vii, x, xi and XII.

³ Many authors have attributed the industrial backwardness of India to the following factors: scarcity of capital, absence of entrepreneurial talent, and social traditions and institutions. For details see V. Anstey, *Economic Development of India* (London, 1957); P. P. Pillai, *Economic Conditions in India* (London, 1925), Ch. x; P. S. Lokanathan, *Industrial Organisation in India* (London, 1938), Chs. i and viii; G. C. Allen, 'The Industrialisation of the Far East', in *Cambridge Economic History of Europe* (Cambridge, 1965), Vol. v, Part II.

⁴ The *laissez-faire* policy of the government was criticised by the nationalist leaders and since then it has been criticised by many authors. For details of these criticisms see A. K. Bagchi, *Private Investment in India, 1900–1939* (Cambridge, 1972), Chs. 2 and 14; S. K. Sen, *Studies in Industrial Policy and Development* (Calcutta, 1964). For the views of the nationalist leaders and newspapers see B. Chandra, *The Rise and Growth of Economic Nationalism in India, 1880–1905* (New Delhi, 1966), pp. 112–22 and pp. 716–32.

Introduction

Its policy of *laissez-faire* and free trade deprived India's industries of the kind of state patronage which they deserved at that particular stage of development and which was being enjoyed by industries in other countries, including the two sister colonies of Canada and Australia.¹ It is true that the influence of the scheme of economic development through international specialisation did not last all through the period of foreign rule. But the change of policy was slow to come and when it came it did not mean an abandonment of the general policy of *laissez-faire* in favour of a positive plan for industrialisation. As a result of the tariff protection which was granted in the 1920s a number of industries benefited.² But the scale of industrial—urban development remained low,³ so that its dynamic impact on the agricultural sector remained insignificant.

As to the research and experimentation with new methods and techniques of agricultural production, the role of the government was in one respect more positive. Public support of agricultural research was available from the turn of the present century when the Imperial Agricultural Research Institute was established. There were also experimental centres under the supervision of the Provincial Department of Agriculture. Successful experiments were made to evolve new varieties of seeds of such crops as jute, cotton, rice, wheat, sugarcane and tobacco. But efforts in the field of demonstration and propaganda remained inadequate. This was due to the fact that from the very beginning the Agricultural Department remained badly understaffed. Though there was normally a trained Agricultural Officer in every district, the number of demonstrators was very small (there were only 130 demonstrators and 23 government farms in the whole province of Bengal). This meant that it was impossible for the District Agricultural Officer to contact a substantial section of the cultivators. As a result the majority of the peasantry remained ignorant of the advances that were being made in the techniques of production.⁴ It was rightly pointed out that by 'far the most important and difficult task before the agricultural officers in India is to bridge the great gulf separating the agricultural experimental stations and

¹ H. G. J. Aitken (ed.). *The State and Economic Growth* (New York, 1959). The economic development of Australia and Canada is discussed in Chs. 2 and 3.

² These are discussed by Bagchi, *op. cit.*

³ In its 'Survey of Indian Industries' made at the end of 1936 *The Economist* commented that 'although India has begun to modernise her industries it can hardly be said that she is as yet being industrialised'. Quoted by Clairmonte, *op. cit.*, p. 133.

⁴ The Bengal Paddy and Rice Enquiry Committee remarked that 'witness after witness told us in course of our tours in the mofussil that the great majority of the paddy growers had never heard of improved seeds and did not know where they could get them from'. For details see, Government of Bengal, *Report of the Bengal Paddy and Rice Enquiry Committee* (Calcutta, 1939), Vol. I, p. 72. See also, *Report of the Bengal Land Revenue Commission* (Calcutta, 1940), Vol. I, pp. 102–3.

the few large-scale farmers from the peasants who cultivate by far the largest portion of land. It is not new science so much as fuller use of existing science that is needed.¹

It is clear that since propaganda was so inadequate the new seed was demanded by only a small percentage of the cultivators. But even this limited demand could not be met by the Agricultural Department. The demand for new seed almost always exceeded the available supply.² There was one area of effort which remained completely untouched. This was the introduction of new artificial fertilizer to aid crop production. The experiments that were conducted with artificial fertilizer were often badly designed and were conducted in a very irregular fashion.³

Thus, the overall situation in Bengal was such that there was neither the availability of modern inputs which would significantly increase yields given the institutional set-up nor a sufficiently favourable economic environment to sustain the large-scale use of new techniques of production by the cultivators. While the first factor was due to the inadequate efforts of the government, the second was caused by the lack of industrial–urban or market development on a sufficient scale.

How would agriculture respond in such an environment? Was the type of specialisation visualised by the classical economists really possible when the growth of population was aggravating the pressure on the available land and the cultivators were virtually left to themselves to effect technological improvement in their production process? It is in any case likely that the foreign demand for raw materials would have led to an expansion of agricultural output. At the time of the establishment of wider commercial contact there must have been a considerable surplus of land and labour in India. The domestic market was too small to absorb the additional output which could be obtained even if there was no technological improvement. In such conditions the expansion of foreign trade, the development of the means of transport, communication and irrigation by the state, the introduction of new crops and the establishment of more stable conditions would be expected to make the agricultural sector much more market oriented than before. Up to this point the propulsive effects of international trade cannot be denied, as it is very likely that the growth of exports would mean an increase in per capita national income shared in different proportion by the different sections of the community.

¹ Sir John Russell, *Report on the Work of the I.C.A.R. in Applying Science to Crop Production in India* (Simla, 1937), pp. 221–2.

² This was admitted in the *Annual Report of the Bengal Department of Agriculture*.

³ See the evidence of C. M. Hutchinson in the *Report of the Royal Commission on Agriculture in India: Evidence, Vol. IV, Evidence taken in the Bengal Presidency* (Bombay, 1927), pp. 296–301.

Introduction

But the more important question that has to be asked is whether the expansion of output would be achieved merely by the extension of cultivation or a new combination of the factors of production. Would specialisation mean merely a movement along the given 'production possibility' curve or would there be technological innovations which would lead to an upward shift in the aggregate production function? Since the cultivators were virtually left to themselves it would seem that increased output would be achieved more by the extension of cultivation than through improvement in yield per acre. Under such circumstances could it not be predicted that after an initial spurt the agricultural sector would again begin to stagnate once the extension of cultivation had reached its natural limits? Further, since the expansion of the agricultural sector would not be accompanied by industrial development on a sufficient scale, would not this stagnation in agriculture given the increasing population create 'disguised unemployment' with its adverse effects on per capita income, the level of investment (even in the traditional factors of production) and on the availability of marketable surplus? In sum, would not the particular conditions in India provide a classic example of 'expansion without growth'?

THE STUDY OF INDIAN AGRICULTURE

There has been a considerable number of secondary works on Indian agriculture. But the attention of scholars has so far remained confined to the estimation of the trends in crop output as 'representative of change in agriculture as a whole',¹ and the main controversy has centred on whether production increased or decreased or remained constant. There is no denying the fact that these trends are the main indicators of the agrarian economy as a whole. But in order to have a better understanding of the underlying trends it is necessary that these should be discussed within a framework comprehensive enough to include, apart from the wider background we have outlined, all the variables which directly or indirectly determine such trends, viz. labour, capital, credit, the price level and the land system. However, even within this narrow scope there are several other limitations in the existing literature. Firstly, in most of these works no attempt has been made to check the officially published data against the data available from independent sources and much less to revise them. Those revisions which have been attempted are mostly elementary or based on guess work. Secondly, most of the works fail to estimate trends in all the major individual crops. The

¹ G. Blyn, *Agricultural Trends in India, 1891-1947, Output, Availability and Productivity* (University of Pennsylvania Press, 1966), p. 19. The findings of the other works are summarised by this author.

obvious result of such an omission is that we lack a detailed picture of the changes in the yields of particular crops which may have taken place in changing circumstances. Lastly, all these works are at the all-India level. Since agriculture is dependent on location and conditions over the sub-continent are not uniform such studies have obvious limitations. The only exception to this pattern (as in the case of trends in individual crops) seems to be the work by George Blyn.¹ He not only estimates the trends in production and their relationship with land and labour but also presents his estimates at the regional level. But here again we do not get an independent picture of Bengal as such since Blyn treats Bengal along with Bihar and Orissa. It is likely that the inclusion of these two other provinces considerably depresses the agricultural trends of Bengal proper.

In the present work an attempt is made to examine the agricultural trends in Bengal proper (i.e. Bengal without the two native states of Cooch Bihar and Tippera) for the period from 1920/21 to 1945/46. As against the limited scope of the existing literature the purpose here is to examine both the trends in crop output and the problems connected with these trends, positive or negative, slow or fast. This approach will focus attention not only on the quantity and the quality of the factors which have direct impact on output, viz. land, labour and capital and the mutual relationships among them, but also on those factors which have indirect influence on growth such as availability of credit, the pattern of institutional control of land and the shifts in the price level. In this way the scope of the present work is considerably more comprehensive.

The present concern for the economic development of the underdeveloped countries has led to a renewed interest among economists in history and this, in turn, has given rise to the 'New economic history'² based on the application of economic theory and statistical techniques of measurement. Paucity of relevant data permits of only a limited application of these techniques in the present study. But as far as possible attempts have been made to use economic theory to explain specific problems or to examine the assumptions made about them at various levels. The need for such an approach has been particularly felt in the examination of such issues as the role of landlords in agricultural development and agricultural indebtedness with all its attendant evils and the attempts made at its solution.

¹ *Op. cit.*

² For discussion on the 'New economic history' see M. Desai, 'Some Issues in Econometric History', *Economic History Review*, Second Series, Vol. xxi (1968), pp. 1–16; R. W. Fogel, 'The New Economic History: Its Findings and Methods', *Economic History Review*, 2nd Series, Vol. xix (1966), pp. 642–56; L. Davis, 'Professor Fogel and the New Economic History', *ibid.* pp. 657–63.

Introduction

We have also tried to present a more detailed and systematic analysis of the trends in the different variables and to test some hypotheses about the production behaviour of the peasantry. For obvious reasons the main focus of attention has been the trend of production and its two determinants – acreage and yield. We have included 13 crops which accounted for more than 90 per cent of the total acreage under cultivation. In order to obtain more reliable estimates of these trends we have revised the officially published data in the light of evidence available from independent sources. The two sets of trends estimated from the revised and unrevised series have been presented both for all-Bengal and the regional units. The method of revision is the most rigorous yet attempted. The problems of capital formation and credit have similarly been examined at the aggregate and regional level. It is believed that such a comprehensive approach and the use of the new research techniques, even in their limited form, will enable us to have a better understanding of the performance of the agriculture of Bengal and its underlying implications during the period under review.

PART ONE

I

NATURE OF CROP STATISTICS AND REVISION

The quality of the basic core of statistics is of primary significance in any quantitative study. But it is in this respect that students of Indian agriculture have been faced with their greatest problem. Statistics had been collected in India in the pre-British period,¹ but it was only in the second half of the nineteenth century that government interest in famine control and in the commercial needs of India led to the creation of a Department of Agriculture, which addressed itself, at least in its early years, primarily to the task of compiling reliable statistics, as this was recognised to be the first step in the direction of agricultural development.² But it is generally believed that, in spite of this long history, agricultural statistics for all parts of India in general and those of Bengal in particular are unreliable. Thus, according to the Royal Commission on Agriculture 'these are merely guesses, not infrequently manifestly absurd guesses'.³ Similar views have been expressed by various other official bodies and individual authors.⁴ Most of them have not, however, referred much to quantitative evidence and their opinions are based on considerations of the defects of the primary agency which collected these data and the methods it used.

In this chapter it is proposed to examine the basis of these beliefs and discuss some of the methodological problems. Could it be argued that the estimation of the different components of crop-output was influenced by the subjective judgement of the reporting agencies even more than usually supposed and, therefore, the officially published data are likely to be more unreliable? This question calls for a re-examination of the official estimating formula and the agencies responsible for making the estimates.

¹ See Lord Meston, 'Statistics in India', *Journal of the Royal Statistical Society*, xcvi (1933), pp. 1-20.

² *Report of the Royal Commission on Agriculture in India* (London, 1928), p. 20.

³ *Ibid.*, p. 605.

⁴ See for example: Govt. of India, *Report of the Indian Economic Enquiry Committee* (Calcutta, 1925), Vol. I, pp. 16-19; Govt. of Bengal, *Report of the Bengal Jute Enquiry Committee* (Calcutta, 1934), p. 82; *Report of the Bengal Paddy and Rice Enquiry Committee* (Calcutta, 1939), Vol. I, pp. 82-9; *Report of the Bengal Land Revenue Commission* (Calcutta, 1940), Vol. I, pp. 76-9; *Report of the Bengal Jute Enquiry Committee* (Calcutta, 1939), pp. 89-91. Opinions of some of the individual authors are referred to later.

I.I THE ESTIMATING FORMULA

The estimating formula used by the Agricultural Department was as follows:

$$O_t = A_t \frac{(S \times C_t)}{100} \quad (1)$$

where O_t = crop output at time t , A_t = area under cultivation, S = standard yield and C_t = condition factor of the same year expressed as a percentage of the standard. For example, if the area under cultivation of a crop was 200 acres, standard yield per acre 1200 lbs and the condition of the current yield 75 per cent of the standard, the output was

$$180\ 000 = 200 \frac{1200 \times 75}{100} \quad (2)$$

I.2 ACREAGE STATISTICS

In the temporarily settled areas where the primary source of crop data was the village accountant or Patwari 'it is generally agreed that the annual figures on areas sown with various crops are on the whole accurate and they compare in this respect very favourably with those published for any other country in the world'.¹ But as revenue demand was permanently fixed in Bengal, the government did not maintain any such staff at the village level and it is believed that the estimates submitted, in the absence of such a staff, by the village watchmen or Chowkidar are 'almost worthless'.²

Did the Chowkidars really constitute the primary agency in the collection of crop statistics? There is no reference either in the *Chowkidari Manual*³ or the *Manual for the Preparation of Crop Reports and Agricultural Statistics* to any such duty assigned to the Chowkidars.⁴ On the other hand, according to the Bengal Paddy and Rice Enquiry Committee the agency responsible for the submission of acreage statistics was to be:

- (a) Preferably a Khash Mahal Tahsildar, if he had duties in the thana which gave him opportunities of judging the area and quality of the crop.
- (b) Next a Circle Officer 'who has been appointed to a circle as a per-

¹ Royal Commission, *op. cit.*, p. 605.

² For such references see, for example, *Report of the Indian Economic Enquiry Committee, op. cit.*, p. 17; R. C. Desai, *Standard of Living in India and Pakistan, 1931–1941*, (Bombay, 1953) p. 7. See also the categorical assertion to this effect by R. S. Finlow and McLean in the *Report of the Royal Commission, op. cit.*, Vol. IV (Evidence Taken in Bengal), p. 14.

³ Bengal Chowkidari Manual (Calcutta, 1916).

⁴ *Manual of Rules for the Preparation of Crop Report and Agricultural Statistics*, (Calcutta, 1922), Third Edition. (Henceforth referred to as *Manual*).

manent measure' provided he must not be asked to submit an estimate for more than a normal Circle of 20 to 40 unions.

(c) Failing the above the Thana Officer.

(d) In addition, either a Kanungo or a District Agricultural Officer might be employed to make an estimate without restriction as to permanency or knowledge of the crop area covered by the estimate.¹

Thus, there is no reference to the fact that the Chowkidars were the primary agency for the estimation of crop statistics. The area for which estimates were made by the Khas Mahal Tahsilders must have been very small as the land revenue of nine tenths of the total area of Bengal was permanently fixed. Therefore, it is reasonable to assume that forecasts were submitted by the Thana and Circle Officers. But it is also obvious that the units (comprising roughly 200 to 400 villages in the case of a Circle Officer) for which such estimates were submitted by the primary agency were too large to enable him to make any objective judgement about the acreage under the cultivation of different crops (and their yield per acre). In this connection it has to be mentioned that neither the Thana nor the Circle Officers belonged to the Department of Agriculture and it seems that compilation of crop statistics was but an additional duty discharged by them. Under the same Rule of the *Manual* the district officers were allowed to 'reject or amend' any estimate 'received from the interior' in the light of their 'knowledge or experience'.² But it is difficult to see how such estimates could have been improved by district officers who had far less knowledge of agricultural conditions as they were in charge of still larger areas.

The defects of the primary agencies were compounded by the rather complicated method laid down by the *Manual* for the compilation of data. Thus, under Rule 7 it was provided that a crop report was to contain an

¹ *Report of the Bengal Paddy and Rice Enquiry Committee*, p. 83. According to this report these were laid down under Rule 5. But Rule 5 of the *Manual* already referred to provides that the 'initial reporting agency should be the same throughout the districts, and the practice under which, in the same district a Kanungo submits estimation for the whole of the sadar subdivision, while elsewhere the police submits estimates for each thana should be abandoned. In most districts the thana should be the reporting unit throughout.' Thus, it is clear that there is considerable difference between this Rule 5 and the one referred to by the above committee. It is, however, possible that the committee was referring to a later edition of the *Manual* which could not be consulted for the present work. The Chowkidars worked under the direct supervision of the Presidents of the village Panchayets. A former President informed me that he had never had any knowledge of the Chowkidars compiling the crop statistics.

² *Manual*, p. 5. It was pointed out to the *Paddy and Rice Enquiry Committee* that the net effect of this provision 'was to reduce the calculation of the crop area to an entirely subjective estimate – an estimate not of informed observers permanently resident in the locality, but of casual visits of itinerant officers, who are required by the rules to sleep only a reasonable number of nights out every month', *op. cit.*, Vol. II, p. 83.

estimate of the area sown with the crop in question in the current year and to compare it with the 'normal area' and the area sown in the previous year. The term 'normal area' was defined as 'the figure which, in the existing circumstances, might be expected to be attained in the year if the rainfall and season were of a character ordinary for the tract under consideration; that is neither very favourable, nor the reverse'. In other words it was defined to be the crop which past experience had shown to be the most generally recurring crop over a series of years. This was not, however, meant to 'imply a mechanically correct arithmetic average which would be misleading'.¹ Evidently the average intended here is the mode of a series, but this is hardly clear from the definition. On the other hand it was pointed out in the *Manual* that there was a tendency to confuse the normal for the maximum area available for the cultivation of the crop. It was found that 'in spite of weather and other conditions having been admittedly favourable to the cultivation of a crop, the area sown is estimated at a figure considerably short of the normal'.² Data presented in Table I.I seem to corroborate this view.³

Thus, except for tobacco and sugarcane, 'actual' area sown is less than the normal area and the discrepancy varies from 3 per cent in the case of summer rice to as high as 26 per cent for sesamum.

TABLE I.I Comparison between normal and 'actual' area

| Crops (1) | Actual area under cultivation (2) | Normal area under cultivation (3) | (2) ÷ (3) % (4) |
|--------------|---|---|-----------------------|
| Winter rice | 15 293.3 | 16 947.2 | 90 |
| Autumn rice | 5 446.0 | 5 743.0 | 95 |
| Summer rice | 406.7 | 418.3 | 97 |
| Wheat | 141.5 | 166.3 | 85 |
| Barley | 88.0 | 113.8 | 77 |
| Gram | 192.4 | 269.6 | 71 |
| Mustard | 752.3 | 911.6 | 83 |
| Sesamum | 168.9 | 229.7 | 74 |
| Linseed | 132.9 | 174.6 | 76 |
| Tobacco | 297.4 | 279.8 | 106 |
| Sugarcane | 298.0 | 202.0 | 148 |

Source: *Season and Crop Report of Bengal*.

All figures are in thousand acres.

¹ *Manual*, p. 7.

² *Manual*, p. 9.

³ This table has been prepared by averaging the acreage statistics for the period from 1920/21 to 1940/41. The latter data is selected in view of the upward trends in the acreage statistics after 1940/41. This will be shown in the appendix.

Nature of crop statistics and revision

The *Manual* further provided that the normal figures were to be revised at the end of every five years in the light of the information obtained from Settlement Records, cadastral surveys and other sources. These were to be further supplemented by the district and other executive officers.¹ It is true that when the Settlement Reports of individual districts were published, the statistics were usually revised accordingly. But there are many instances when figures on 'normal' areas were revised without reference to any changes in their underlying determinants. This was frequently done even for districts where figures were available from the Settlement Reports.

The presumption that these weaknesses in the estimating formula and primary reporting agencies made the acreage statistics unreliable, and indeed more unreliable than usually supposed, is borne out by three sets of quantitative evidence – *District Survey and Settlement Reports*, *Agricultural Statistics by Plot to Plot Enumerations* and the *Sample Surveys* made by the Indian Statistical Institute. As already mentioned the defects of the crop statistics were pointed out from time to time by official bodies and individual authors. But it was only in the 1940s that steps were being taken by the provincial government to remedy the situation. The most important of these was the Plot to Plot Enumeration of 1944/45 conducted under the supervision of the then Development Commissioner, A. H. M. Ishaque.² The most immediate urge in this direction, however, came from the experience of the famine of 1943 and the necessity of obtaining, for the success of the Grow More Food Campaign, a clear picture about the pattern of land use in Bengal. Statistics available from this Report are the most reliable and detailed of their kind in the whole of the sub-continent. But, except for the case of autumn rice, sugarcane and sesamum, no direct comparison between the departmental estimates and the findings of this Report is possible, as the Agricultural Department, instead of submitting their own estimates for 1944/45, published the figures available from the Ishaque Report. Such a comparison would not, however, have been meaningful even if the official figures were available. This is due to the fact that there was considerable upward revision of the acreage data from 1941/42 (see Appendix). This makes it once again difficult to attempt any direct comparison.

Thus, it is clear that the findings of the Ishaque Report do not directly reflect the margin of error involved in the official acreage data. In order to obviate this difficulty, predicted values of the departmental estimates for

¹ *Manual*, p. 5.

² *Agricultural Statistics by Plot to Plot Enumeration in Bengal, 1944/45*, 3 Parts (Calcutta, 1946). (Henceforth referred to as Ishaque Report.)

1944/45 have been obtained by fitting the least square trend line and these are then compared with the figures available from the *Plot to Plot Enumeration*. In the case of sugarcane and sesamum the comparison is made directly between the official estimates and the figures available from the Ishaque Report. In the case of autumn rice the figures from this Report are compared both with the predicted values of the official estimates for 1944/45 and the actual estimates which were published. The comparative picture which emerges from this procedure is presented in Table 1.2. This shows that the official figures on the acreage under sesamum, sugarcane and tobacco are overestimated and in the case of other crops these are underestimated and that the error in total crop acreage is in the direction of underestimation. In the case of autumn rice comparison between predicted official estimates and the findings of the Ishaque Report shows that the official figures are underestimates. But the direction of error is just the opposite when comparison is made between the actual official estimates for 1944/45 and the figures

TABLE 1.2 *Predicted values expressed as a percentage of the figures from the Ishaque Report*

| Crops (1) | All-Bengal (2) | Presidency (3) | Burdwan (4) | Rajshahi (5) | Dacca (6) | Chittagong (7) |

* Official estimates expressed as a percentage of the figures from the Ishaque Report.

Nature of crop statistics and revision

available from the Ishaque Report. For reasons to be discussed later on it is assumed that the official data on autumn rice up to 1940/41 are also underestimates. It is significant that except in the case of sesamum the forecast figures are overestimates in those cases where the 'actual' area exceeds the normal acreage under such crops (Table 1.1). However, at the regional level the margin of error is not in the same direction in all the cases.

A second independent check in the case of winter rice, autumn rice and jute is provided by the findings of the sample surveys conducted by the Indian Statistical Institute. For reasons already referred to, here again direct comparison between these findings and the official forecast figures does not reflect the real margin of error in the latter. Secondly, acreage under the cultivation of jute was statutorily regulated from 1941/42 and it is, therefore, possible that the margin of error in these years was less than previously. What is, however, significant is that the direction of error remains the same, except in the case of autumn rice of 1945/46 (Table 1.3).

Another independent check is provided by the figures available from the Reports on the Survey and Settlement Operations in the districts. Here again, there is one important limitation. These operations were started in 1888 and by 1920 ten districts (comprising 46 per cent of the total area of Bengal) were surveyed. The survey operations for the remaining seventeen districts were completed by 1940. During this long period the acreages under the cultivation of different crops must have changed implying changes in the relative weights of particular crops in the total crop mix. Some idea of

TABLE 1.3 *Comparison between survey and official estimates of acreage*

| Crops (1) | Years (2) | Survey estimate (3) | Official estimate (4) | (4) ÷ (3) % (5) |
|--------------|--------------|---------------------------|-----------------------------|-----------------------|

| Winter rice | 1944/45 | 22 201 | 18 952 | 84 |
| | 1945/46 | 21 087 | 19 471 | 92 |

Source of the Survey estimate: Desai, *op. cit.*, p. 8.

In the case of Winter rice for 1944/45 the comparison is against the figures compiled by the Agricultural Department by the 'usual procedure'. See *Calcutta Gazette*, Vol. CLVIII, No. 2049, p. 532. All figures are in thousand acres.

such changes may be gained from Table 1.4 in which figures available from the Survey Reports are compared with the findings of the Ishaque Report.

These increases in the crop acreage, with the sole exception of sesamum, are once again reflected in the area designated as net cropped area, double cropped area, cultivable waste and current fallow. In view of this consideration it is not possible to make any estimate of the magnitude of error in the official acreage statistics by comparing these with the settlement figures. Strictly speaking, this is true even in the case of particular districts as it took several years (as many as 10 years in the case of Rajshahi district) to complete the survey operations. But even then the indications are unmistakeably clear. Table 1.5, in which the average of the official data for five years ending 1939/40 are compared with those available from the Settlement Reports, confirms the earlier finding that there is a considerable margin of error in the former. It is again significant that the direction of error in individual crops remains the same as in Table 1.2.

In the case of jute there are other independent sources which contain evidence to show that the official estimates on acreage are underestimates. For example, there is the 'actual' total of jute production as ascertained from trade statistics and village retention. The year-to-year discrepancies between the official estimates and such 'actuals' are presented in Table 1.6. This shows

TABLE 1.4 *Comparison between settlement figures and data in the Ishaque Report*

Note: All figures are in thousands.

that except for two years, 1929 and 1939, the departmental forecast figures on production are always underestimates.¹ It has already been shown (Table 1.3) that the error in the three years from 1943/44 to 1946/47 is due to the underestimation in acreage statistics. The same trend emerges from the findings of the Ishaque Report and another plotwise enumeration made in 1940/41. Compared with these findings the official data on acreage are found to be underestimated by 17 per cent in the case of the former and 52 per cent in the case of the latter. In a later section it will be shown that the yield per acre of jute was overestimated by the Agricultural Department. The fact that in spite of this overestimation official estimates of jute production remained lower than the 'actuals' would suggest that the officially published figures on jute acreage remained underestimates in the earlier period.² This unreliability in the acreage data on jute is of particular significance in view of the fact that, unlike other crops, these estimates are said to have been

¹ These figures also include production on jute in Bihar, Orissa, Assam and Cooch Bihar. But only a small quantity of jute was produced in these areas. It is reasonable to assume that the direction and margin of error here are representative of Bengal. The Department of Agriculture sometimes revised upward the final forecast figures on acreage and production. The margins of error indicated in this table would be bigger if comparison were made between final forecast figures on production and 'actuals'.

² It will further be argued that the margin of error was indeed bigger than indicated in this table.

Bengal agriculture 1920–1946

submitted by the presidents of the village panchayets and for this reason they have been regarded as reliable.¹ Secondly, from 1941/42 the acreage under jute cultivation was controlled under the Jute Regulating Act of 1941.

I.3 STANDARD YIELD

The two other elements in the estimating formula of the final output of a crop are the 'standard yield' and the 'condition factor'. Both of these elements

¹ *Manual*, p. 13.

have been strongly criticised from time to time, but it is only recently that attempts have been made to quantify the magnitude of error involved in them. Estimates of standard yields were worked out at the end of every fifth year on the basis of the crop-cutting experiments made during the preceding five years. Such estimates, once worked out, were taken to be the standard yield of the crops for the next 5 years. The definition of standard yield is the same as that of 'normal area' and as already mentioned was itself very confusing.¹ But there were other limitations to this procedure, as was pointed out by the National Income Committee. The experiments made by the district officials were not based on random sampling but on purposive sampling. Neither the size of the plot nor the number of experiments was adequate for the purpose of generalisation. The normal yield which was thus worked out was taken to be the normal yield of the entire district irrespective of variations within the district.² Some idea of the extent to which the subjective judgement of the officials was at work in the whole process of working out the standard yield may be gained from the fluctuations of the figures on standard yield at different quinquennial periods (Table 1.7). It seems that the explanation for these variations has to be sought more in the influence of the personal judgement of the officials than in any change in the underlying determinants of yield.

TABLE 1.7 *Standard yields in the quinquennia*

| Crops | Standard yield of quinquennium beginning | | | | | |
|-------------|--|---------|---------|---------|---------|---------|
| | 1916-17 | 1922-23 | 1927-28 | 1932-33 | 1937-38 | 1942-43 |
| Winter rice | 1036 | 1029 | 1022 | 1111 | 1030 | 1020 |
| Autumn rice | 871 | 888 | 892 | 1023 | 914 | 865 |
| Jute | 1387 | 1387 | 1387 | 1387 | 1387 | 1387 |
| Gram | 867 | 826 | 811 | 935 | 833 | 738 |
| Wheat | 698 | 688 | 721 | 816 | 788 | 685 |
| Mustard | 480 | 485 | 483 | 624 | 571 | 535 |
| Sesamum | 404 | 503 | 495 | 610 | 580 | 529 |

| Sugarcane | 2963 | 3004 | 3054 | 4643 | 4446 | 4388 |

Source: standard yield figures are available from *Estimates of Area and Yields of Principal Crops in India* (*op. cit.*) and the quinquennial reports on the crop-cutting experiments mentioned later in this chapter. The standard for jute is the simple average of the divisional averages which remained fixed from 1913. All yields are in lbs.

¹ *Ibid.*, p. 7.

² Govt. of India, *Final Report of the National Income Committee* (Delhi, 1954), p. 25.

This is further suggested by the comments made from time to time by different officials to justify these variations. Thus, while submitting the Report on the crop-cutting experiments in 1922 G. Evans, the Director of the Agricultural Department, pointed out that the standard yields were not more accurate than in the past except in the case of jute and that reliability could not be 'guaranteed' unless the whole work of the crop-cutting experiments was taken up by the Department of Agriculture from the Department of Revenue.¹ But in the next report submitted in 1927 it was argued that the 'present rates of yield may be regarded as fairly accurate' as yields in almost all the crops remained stationary.² The criterion of reliability again changed in 1932 when it was argued that as most of the experiments in the preceding quinquennium were made by the 'trained officers of the Agricultural Department with due care and accuracy greater reliance can be placed on the data on which the average yields have been based'.³ The standard yields of all the crops showed a decline in the next quinquennium. This was ascribed to the deficient and very uneven distribution of rainfall during large parts of the previous five years.⁴

However, the usual assumption that the standard yield figures are unreliable is once again borne out by the findings of crop-cutting experiments made by the Indian Statistical Institute under the supervision of Professor P. C. Mahalanobis. A comparison with the figures on the yields of the three most important crops estimated by the Indian Statistical Institute shows that the standard yields worked out by the Agricultural Department are over-estimates in all the quinquennial periods (Table 1.8).

The margin of error in the standard yield reaches the highest point in the figures worked out for the quinquennium beginning 1932/33. The explanation seems to lie in two changes introduced in this quinquennium. On an examination of the returns in 1911/12 it was admitted by the Government of India that the results were not reliable and accordingly the provincial governments were asked to transfer the crop-cutting experiments to the Department of Agriculture. But except for the case of jute this could not be

³ Govt. of Bengal, *Quinquennial Report on the Crop-Cutting Experiments for the Years 1927/28 to 1931/32* (Calcutta, 1932), p. 3.

⁴ Govt. of India, Director General of Commercial Intelligence and Statistics, *Quinquennial Report on the Average Yield Per Acre of Principal Crops for the Period Ending 1936/37* (Calcutta, 1941). This argument is, however, contradicted by the evidence on seasonal conditions except for the cases of winter and autumn rice.

Nature of crop statistics and revision

TABLE 1.8 Standard yield expressed as a percentage of survey estimates

| Quinquennium beginning | Winter rice | Autumn rice | Jute |
|---------------------------|----------------|----------------|------|
| 1916/17 | 145 | 133 | 121 |
| 1922/23 | 144 | 136 | 121 |
| 1927/28 | 143 | 136 | 121 |
| 1932/33 | 155 | 156 | 121 |
| 1937/38 | 144 | 140 | 121 |
| 1942/43 | 143 | 132 | 121 |

Note: Figures on the actual yields estimated by the Indian Statistical Institute are shown in Table 1.10. The standard yield of jute remained fixed from 1913.

done before quinquennium beginning 1927/28. As already pointed out, in the Report submitted in 1932 it was argued that as the majority of the experiments were made by 'trained' officers of the Agricultural Department the standard yield figures could be taken as reliable. It is not known if the procedure of crop-cutting experiments improved at all as a result of this transfer.¹ On the other hand, it is believed that in at least one respect the position deteriorated. The transfer of the crop-cutting experiments coincided with the increased endeavour on the part of the Department of Agriculture to popularise the improved varieties of seeds evolved at the experimental centres. It is possible that the increase which was known to have taken place from the records of the areas sown with selected seeds was very 'imperfectly shown in the figures. This may be the cause of the excess of the yield shown by the recent crop-cutting experiments over the standard'.² This increase in yield would have been much smaller if the former practice of averaging the standard yield estimated at the end of a quinquennium with the figures of the previous two quinquennia had been adhered to. But this was abandoned.³ This practice was, however, revived in the next quinquennium when the average yield of all the crops estimated from the results of the crop-cutting experiments showed a decline.⁴

¹ The Royal Commission recommended that every provincial Department of Agriculture should have a Statistical Officer, see *Report*, p. 617. But this was not compiled with.

I.4 CONDITION FACTOR

The estimation of the condition factor was completely based on subjective judgement and is, therefore, likely to be even more unreliable. Under Rule 25 of the *Manual* the primary reporting agencies and the district officials were required to estimate the condition of current yields in terms of annas.¹ From this it seems that the same agencies (Circle and Thana Officer and Tahsilder) who submitted the acreage statistics also estimated the seasonal condition of the current yield, though here again, the usual assumption has been made that these were provided by the Chowkidars.² Yield per acre depends on far more numerous factors than does acreage under cultivation and these are more likely to escape the visual impression of the reporting agencies on the basis of which estimates were made. Therefore, the contention that the guesses made by the officials about acreage under cultivation could not but be unreliable applies to the forecast of the seasonal condition with greater force.³ Again, as in the case of the acreage statistics this basic defect was compounded by the procedure which was laid down for quantifying the seasonal condition. Under the same Rule it was provided that 12 annas was to represent a normal crop and 16 annas a bumper one. This 'annawari' estimate was converted into a percentage estimate in the office of the Director of Agriculture.⁴ But the significant feature that emerges from the figures

TABLE I.9 *Index of Condition Factor*

| Crops | 1924–25 | 1929–30 | 1934–35 | 1939–40 | 1944–45 |
|-------------|---------|---------|---------|---------|---------|
| Winter rice | 92 | 91 | 91 | 88 | 82 |
| Autumn rice | 80 | 77 | 87 | 75 | 80 |
| Wheat | 74 | 75 | 79 | 76 | 72 |
| Gram | 65 | 66 | 77 | 73 | 74 |
| Linseed | 70 | 68 | 75 | 73 | 71 |

⁴ *Manual*, *op. cit.*, p. 12.

Nature of crop statistics and revision

presented in Table 1.9 is that in almost every year the yield per acre is below the normal or standard.

Attempts have been made to explain these lower 'annawari' estimates in different ways. The one reason which has been most widely referred to is the supposed pessimism of the village Chowkidars. Thus, it was pointed out by Meek that the Patwari or the Chowkidar 'being generally untrained and generally pessimistic by nature is hardly able to form a correct estimate of the outturn in terms of the normal crop. His idea of a normal crop is that which he longs to see but rarely sees and the result is that the standard with which he compares a crop is really something above the normal. Consequently his estimates generally fall below the mark'.¹ As already pointed out, it is doubtful if the Chowkidars really submitted any crop estimates. However, a comparison with the actual yields of three major crops estimated by the Indian Statistical Institute does not at all show that the primary reporting agencies were pessimistic (Table 1.10). Thus, except for jute in 1942/43 and 1943/44 when crop-cutting experiments were made respectively in 9 and 15

Yield figures on winter rice for 1945/46 are taken from P. C. Mahalanobis, 'Recent Experiments in Statistical Sampling in the Indian Statistical Institute', *Journal of the Royal Statistical Society*, Part IV, 1946, p. 344.

¹ *Report of the Royal Commission, op. cit.*, Evidence, Vol. I, Part II, p. 358. The same view was taken by the Director of the Agricultural Department, Govt. of Bengal, Vol. IV, p. 14. See also, H. Sinha, 'Indian Agricultural Statistics', *The Journal of the Royal Statistical Society*, 1934, Part I, pp. 155–62.

districts, and for autumn rice in 1944/45, the official yield per acre is an overestimate.

Discrepancies between the findings of the Indian Statistical Institute and the 'actual' yield per acre estimated by the Agricultural Department in the quinquennial periods are presented in Table 1.11. The pattern remains the same as in the last quinquennial period – the official yield figures are overestimates.

Thus, on the basis of these findings, it may be concluded that the primary reporting agencies overestimated the yield per acre. It is, however, interesting that the range of error is smaller than in the case of the figures on standard yield. In many cases the range of overestimation would have been still lower if crop output were always estimated on the basis of reports submitted by the primary agencies. There are many instances in which the condition factors on winter and autumn rice for the whole province as worked out from the 'annawari' estimates of the districts were revised upward by the Director of Agriculture, because he believed that the condition of the current yield was much better than that reported.¹ This suggests that the primary reporting agencies were aware of the fact that the standards were pitched high and, therefore, deliberately put the 'annawari' estimates below the normal.² Another possible explanation for this practice is provided by the fear expressed by the Agricultural Department with regard to the acreage statistics – that there was a tendency on the part of the reporting agencies to confuse the normal with the maximum.³

Some authors believe that the primary reporting agencies tended to overestimate bad years and underestimate good ones.⁴ In the absence of any positive evidence to indicate the true position regarding the yield per acre it is difficult to say anything about the merit of such an assumption. What is, however, important is that such a tendency, even if true, does not seem to create any problem so far as the measurement of the trend rate is

¹ So far as Bengal is concerned this evidence contradicts Desai's (*op. cit.*, p. 13) assumption that sometimes the Director of Agriculture tried to correct the overestimation in the results of selected crop-cutting experiments.

² W. C. Neale has suggested the possibility that the suppression of the increase in yield per acre was due to the nationalist politics of the 1920s and 1930s which wanted the foreign government discredited. See his *Economic Change in Rural India: Land Tenure and Reform in Utter Pradesh, 1800–1955* (Yale University Press, 1962), p. 45. So far as Bengal is concerned the evidence presented here suggests an opposite possibility. For further evidence of how the standard yield figures for the quinquennium beginning 1937/38 were distorted by Finlaw, the Director of Agriculture, see *Paddy and Rice Enquiry Report*, Vol. II, p. 18.

³ *Manual*, p. 9.

⁴ *National Income Committee*, p. 27. The same view has been taken by V. G. Panse, 'Trends of Areas and Yields of Principal Crops in India', *Agricultural Situation in India*, Vol. VII, No. 3 (June 1952), p. 144.

concerned. For, if there were the same number of bad years and good years within the period under review it is possible that the overestimation and underestimation approximately cancelled each other out to leave the trend rates unaffected.¹

Another aspect of the procedure of estimating the seasonal condition which has been given considerable importance is the fact that the condition could be expressed in the form of an integral number of 'annas'.² Because of this practice, it has been argued, when the 'annawari' estimates were first reported they were likely to be in excess of or below the true value by up to half an anna. The error could not have been a serious one in the case of a nearly normal crop, but for a crop much below the normal it could be large. If the errors were random, the ultimate margin of error would have been small. But it has been further argued that these were systematic and, therefore, the condition factor as finally worked out is much smaller than the actual figure by a large percentage. In the case of Bengal, however, such an error seems to have been very small. Firstly, Rule 25 of the Manual required the primary reporting agencies to submit the estimates of the seasonal condition not only in terms of an integral number of annas but also in terms of fractions of annas. Fractions could be ignored only if smaller than one tenth. Secondly, under the same Rule a weighted average of the anna outturns of a crop in the different parts of the district was taken to represent the district estimate.³

The procedure of estimating the seasonal condition of yield was different in the case of jute. The average yield of jute for every district was estimated by the Director of Agriculture after consultation with the district officers. The basis was the results obtained from cropcutting experiments and information from cultivators who had harvested their crops.⁴ The average yield

TABLE I.II *Range of error in the yield of rice and jute* (percentage overestimation (+) or underestimation (-) in the quinquennial yield per acre)

| Crops | 1920-24 | 1925-29 | 1930-34 | 1935-39 | 1940-44 |
|-------------|---------|---------|---------|---------|---------|
| Winter rice | + 28 | + 26 | + 28 | + 30 | + 19 |
| Autumn rice | + 7 | + 3 | + 15 | + 9 | + 10 |
| Jute | - 7 | + 6 | + 12 | + 10 | + 3 |

³ Manual, p. 11.

⁴ Manual, p. 13.

so obtained was then expressed as a percentage of the divisional normal fixed in 1913. The seasonal condition which was thus worked out considerably reduces, but does not fully offset, the high margin of error in the standard yield. It is only in the fourth quinquennium that the direction of error changes.

Discrepancies between the 'actual' and estimated production of jute have already been presented in Table 1.6. Now the evidence that the official data overestimate the yield per acre of jute largely substantiates the assumption already made: that the real magnitude of error in the acreage statistics is much larger than indicated in this table.¹

1.5 DIFFICULTIES IN ASSUMING UNIFORM RANGE OF ERROR

From the preceding discussion it is clear that the official acreage statistics are in most cases underestimates and the yield figures overestimates. But as most of the existing works on Indian agriculture are at the aggregate level, no attempt has been made to quantify fully the range of error and much less to revise the official statistics in the light of the independent data available.² At the all-India level a problem which has been faced more squarely is the non-availability of crop statistics for certain areas.³ So far as the error in the available statistics is concerned it has usually been argued, though on different assumption by different authors, that such errors would not introduce any significant bias into the trend rates.

Thus, according to Thomas and Shastry, for the purpose of comparison between the trends of population and food supply the deficiencies of the agricultural statistics are not serious, 'because the errors are more or less systematic'. They further argue that if the 'annawari estimates are more or less guesses, they have been so for the whole period under consideration. Therefore whatever error there is, is common for the whole period.' Thus, according to these authors the crop statistics, though inadequate for the estimation of total food supply are helpful for time comparisons.⁴ Blyn proceeds on the same assumption and argues that 'neither the degree of error nor the likelihood of an error distribution making for maximum bias,

¹ *The Bengal Jute Enquiry Committee* of 1939, however, argued that the standard yield figures were not as unreliable as they were made out to be. The committee further erred in assuming that the crop-cutting experiments were made by the Presidents of the Union Boards. See Report, Vol. 1, *op. cit.*, p. 90.

² There seems to be only one such study, K. L. Datta, *Report on the Enquiry into the Rise of Prices in India* (Calcutta, 1914). Some adjustments are also made by Desai and Blyn, *op. cit.* These will be commented upon later on.

³ For example see Blyn *op. cit.*, and Mukerji, *op. cit.*

⁴ P. J. Thomas and N. S. R. Shastry, *Indian Agricultural Statistics* (University of Madras, 1939), p. 89.

was sufficiently large to significantly affect the British India trend rates for aggregates of crops over the whole period'.¹ Mukerji accepts the assumption made by Panse that there was a tendency among the crop reporters to overestimate production in bad seasons and underestimate it in good ones – and argues that the tendency towards underestimation is of a comparatively recent origin: the late twenties. Therefore, he concludes that 'for the purpose of general comparison over a long period of fifty years or more this element of underestimation is not likely to be of great significance. On the whole, therefore, it would seem that working on the basis of agricultural output figures corrected for uniform coverage, subject to certain recognised shortcomings that have already been noted, is justified'.² The same conclusion could be drawn on the basis of an opposite view put forward by Subramaniam. He argues that if the errors were random ones the successive averaging may be expected to make the error as small as possible. But these errors are systematic ones and are known to have strong downward bias.³ In such a case the height of the trend line would be affected, but not the rate of change.

On *a priori* considerations it is difficult to accept any of these hypotheses to the complete rejection of the others. But in the light of the evidence already presented, Subramaniam's assumption seems to be the most relevant one for the acreage statistics up to the year 1940/41. From the point of view of individual crops, however, the position of Bengal seems to justify the assumptions of both Thomas and Shastry on the one hand and Subramaniam on the other in the sense that acreage statistics on certain crops are underestimates and those on others overestimates and the margin of error remains uniform up to the year 1940/41. On inspection of the acreage data presented in the Appendices it seems that there are only four crops – sugarcane, jute, sesamum and gram – where this underlying assumption does not hold good. It seems that the volume of underestimation in gram is reduced from 1936/37 and that of overestimation is increased in the case of sesamum and sugarcane respectively from 1937/38 and 1931/32. For jute the range of error is more marked in the first quinquennium and the depression period. Then the general pattern changes, beginning from 1941/42 in the case of winter rice and autumn rice, and 1942/43 in the case of other crops, when the upward movements in the acreage statistics started. The only exceptions are seen in the case of sugarcane and tobacco. The series remains

¹ Blyn, *op. cit.*, pp. 55–6. He concedes that there could be some improvement in the accuracy of the estimates but argues 'some of the bias which would have resulted from this was removed, however, by the adjustment of the yield per acre series where changes in the parameters of estimation evidently occurred'.

² Mukerji, *op. cit.*, p. 21.

³ Subramaniam, *op. cit.*, pp. 3–4.

stable in the case of the first and for the latter there is a drop in the acreage under cultivation.

In the official publications these increases were variously described as due to the 'Revision of Estimates', 'Success of the Grow More Food Campaign' and 'Favourable weather conditions'.¹ It is possible that there was an extension of cultivation as a result of the Grow More Food Campaign and a relative shift in the acreage under food crops in view of the famine. What, however, seems to be certain is that such increase was very marginal.² Under the conditions of an adverse man-land ratio and the inadequacy of food supply it is difficult to see why before 1941/42 the acreage under the cultivation of all crops, particularly of rice, should have decreased to such an extent as to be much lower than even the figures ascertained by the cadastral surveys. It is well known that the physical and climatic conditions of Bengal should have made the extension of cultivation to the possible limits relatively easy. Therefore, when the growth of population was pressing upon the available food supply it is reasonable to believe that the scope for the extension of cultivation in the 1940s was not as big as it was made out to be by the Agricultural Department. These considerations make it fairly clear that by showing the increase in the acreage data as due to the success of the Grow More Food Campaign and favourable weather conditions the Department was actually reducing the margin of underestimation in the acreage data. The only exceptions seem to have been sesamum and mustard where the margin was being increased. It is significant that the Agricultural Department did not ascribe all the increases to these factors either – as mentioned above, in a large number of cases these were accounted for by the revision of estimates. It is further significant that, in contrast with earlier years, these revisions were almost uniformly in the upward direction.

I.6 PROPOSED PLAN OF REVISION

From the preceding discussion it is quite clear that the assumption that the range of error (whether in the direction of overestimation or underestimation) was uniform over the entire period, leaving the percentage rate of change more or less unaffected, does not hold good in the case of Bengal. Therefore, it is proposed to revise the acreage statistics of all the crops by taking the

¹ Any increase or decrease of 10 per cent or upward in the acreage data of a year from those of the preceding year was accounted for in the *Agricultural Statistics of Bengal* (annual).

² This was also the belief of contemporaries. Thus Dr Rao commented that the campaign was 'being criticised all over the country both by economists as well as by laymen' and that the real increase under food crops brought about by this campaign was smaller than claimed by the Government. See his article, "Grow More Food Policy" in India', *The Indian Journal of Agricultural Economics*, Vol. iv, No. 1 (March, 1949), p. 239.

findings of the Ishaque Report as point estimates. However, the trend rates of the official series on acreage and output are also measured and presented along with those of the revised data to facilitate comparison.

As already mentioned, Panse has argued that there was a tendency among the crop reporters to overestimate production in bad seasons and underestimate it in good ones. Mukerji extends this thesis to the case of the acreage under cultivation and argues that 'the acreage of particular crops would have a tendency to be underreported when, for one reason or another, there is a tendency for acreage and production of that particular crop or particular group of crops to increase. Any measure of underestimation of crop acreage on the basis of the figures of a particular year is, therefore, not likely to provide one with a measure of under-reporting that can be used for correcting the officially published figures for crop output'.¹ It is not known how far this assumption is valid at the all-India level. But so far as Bengal is concerned the available evidence does not seem to substantiate the type of relationship suggested by Mukerji.² Thus, the difficulty seen by him in the way of the proposed revision does not seem to be genuine.

Such a difficulty may, however, be seen to arise from a different consideration. The acreage data show a good deal of fluctuations from year to year. This raises the question as to how far the predicted values of the departmental estimates for 1944/45 can be taken as a proxy for the actual estimates which would have been made had the Grow More Food Campaign not been launched and had the Plot to Plot Enumeration not been undertaken. If it is argued that such actual estimates would have been higher than the predicted values, it is clear that the discrepancies which are observed exaggerate the range of underestimation. The situation would be reversed if, on the other hand, it were argued that such values would have been lower than the predicted values. Obviously it is not possible to make any guess as to whether the actual estimates would have been lower or higher or fortuitously similar to the predicted values. But as a matter of fact these are, again, not genuine difficulties in the way of the proposed revision. The discrepancies observed between the findings of the Ishaque Report and the predicted values may exaggerate or underestimate the actual range of error in the official series, but under the proposed plan these are being uniformly distributed.

Technically, there are two problems which pose a real difficulty. Firstly, no allowance is being made for any seasonal fluctuations in the years for which different adjustment factors are being used, i.e. 1941/42 to 1943/44

¹ Mukerji, *op. cit.*, p. 21.

² See chapter 2, 3 and 4.

in the case of winter rice and 1942/43 and 1943/44 in the case of other crops excluding sugarcane and sesamum. Secondly, no account is being taken of any increase which may have been due to the Grow More Food Campaign and a run of favourable weather conditions. But it seems that the effect of these factors on the percentage rate of acreage change will be very marginal.

Before proceeding further to discuss the details of the planned revision, adjustments of the available data made by some authors will briefly be reviewed. It is convenient to start with the important work by Datta. He rejects the figures on acreage under cultivation, standard yield and condition factor as these had their origin in the guess work of the Chowkidars and revises the data in the light of the first-hand data which he and his assistants were able to obtain from their tours. Thus, Datta revises all three components of crop output. It seems that his assistants were neither the regular officials of the Agricultural Department nor residents of the locality for which they supplied the data. Therefore, it is reasonable to assume that they had much less familiarity with the agricultural conditions of the country than the usual crop reporters. Thus, it is difficult to see how statistics obtained by such enquiries could be any better than the ones submitted by the regular agencies. This is particularly so in view of the fact that the conditions of the great variety of crops, both with regard to acreage under cultivation and yield, differ so much between the different parts of the subcontinent.

Blyn's primary interest is in making adjustments for areas for which acreage or yield or both were not reported and in this respect his work is a significant contribution. But in doing so he also revises the yield figures of some crops for Madras, Bombay–Sind and United Province relating to certain years, as it appears to him that there is no real basis for the radical jump in the yield for those years. Therefore he assumes that the changes were due to differences in the government's crop estimation, and he raises (or lowers) the yield for all years up to the year of change by the percentage required to make the straight-line trend of that year equal to the straight-line trend in the following period projected back. There seems to be hardly any doubt about Blyn's basic assumption nor much objection against his method of correction as such. As already shown a more or less similar situation is noticed in Bengal in the early thirties when the crop-cutting experiments were transferred to the Department of Agriculture. It has also been argued that the quinquennial averages of yield which are expected to be free from the influence of seasonal fluctuations show considerable difference in many cases and that the explanation for this has to be sought mainly in the differences in the subjective judgement of the reporting agencies. But it seems that in building up a reliable estimate of crop output for the whole sub-continent it

Nature of crop statistics and revision

is not sufficient to correct the figures of one or two Provinces alone. For, apart from Madras and Bombay there are many other Provinces in which radical changes are noticed in the yield of particular quinquennia (Table 1.12). Obviously these changes are as much the result of changes in the government's crop estimation as observed by Blyn in Bombay-Sind, Madras and United Province. But he does not attempt any correction in such cases. Thus, his estimates of all-India crop output are only partially corrected.

Finally, the important work by Desai may be referred to. His method of correction of the available statistics is more straightforward and the coverage is once again very incomplete. For example, so far as Bengal is concerned, he finds that the three independent sources already referred to indicate, on average, an underestimation of 10 per cent in the acreage under the cultivation of rice and he, therefore, revises the data accordingly. It has already been pointed out that any direct comparison against the figures available from these three sources cannot be expected to reflect the real volume of error in the official data. On the other hand according to the procedure followed in this work it is quite clear that the margin of error is much bigger. Again, the underestimation in the acreage under the other crop of Bengal corrected by him — gram — is much larger than the twenty-five thousand acres which he adds to the officially published data. Desai does not change the yield per acre and the only adjustment in the official estimates of output is caused by the correction of the corresponding acreage data. But in the light

TABLE 1.12 *Fluctuations in the yield of certain crops in other provinces*

| Crop (1) | Province (2) | Years (3) | Yield (lbs) (4) | Yield (lbs) (5) | Yield in next 5 years (5) ÷ (4) (%) |
|-------------|------------------|--------------|-----------------------|-----------------------|---|
| Rice | Sind | 1931-35 | 961 | 853 | 89 |
| Rice | United Province | 1936-40 | 628 | 556 | 88 |
| Wheat | Central Province | 1921-25 | 645 | 418 | 65 |
| Jowar | Sind | 1931-35 | 415 | 366 | 88 |
| Barley | United Province | 1931-35 | 919 | 785 | 85 |
| Gram | United Province | 1921-25 | 751 | 589 | 78 |
| Gram | Central Province | 1921-25 | 579 | 386 | 64 |
| Sugarcane | Punjab | 1936-40 | 1749 | 2425 | 139 |
| Sugarcane | Bombay | 1931-35 | 5906 | 4910 | 83 |
| Sugarcane | Bombay | 1936-40 | 4910 | 6960 | 142 |

Source: Blyn, *op. cit.*

of the evidence presented, to the effect that yield figures are generally over-estimated, it seems that this procedure is once again defective. The primary interest of Desai's work is in building up an estimate of consumer expenditure in the sub-continent. Therefore, in contrast with the present work, it is not the percentage rate of change but the estimation of the physical volume of crop output which is important. Considered in this context his method of correction and its coverage of only a few crops seems to be of considerable significance.

The details of the revision are as follows: acreage data on winter rice up to 1940/41, and those on net cropped area, double cropped area, current fallow, cultivable waste, summer rice, wheat, barley, gram, tobacco and mustard up to 1941/42 are revised according to the formula:

$$R_i = F_i \left(\frac{I}{P} \right) \quad (3)$$

where R = revised figures, F = official forecast figures, P = volume predicted by official estimates for 1944/45, I = figures from Ishaque Report and i = accounting year (1920/21 to 1940/41). The product of I/P is called the adjustment or revision factor. Thus, if the acreage under the cultivation of a crop for a particular year, say 1920, was 1800 acres, the predicted values for 1944/45 2000 acres and the corresponding figure from the Ishaque Report 2300 acres, the revised data would be:

$$2070 = 1800 \left(\frac{2300}{2000} \right) \quad (4)$$

with an adjustment factor of 1.15.

The formula used for the period 1941/42 to 1943/44 is as follows:

$$R_i^* = F_i^* \left(\frac{P_i^* \frac{I}{P}}{F_i^*} \right) \quad (5)$$

where R_i^* = revised figure for the year i , F_i^* = forecast figure for the year i and P_i^* = predicted value for the year i . In other words this means that the forecast values are replaced by the product of the predicted values and the adjustment factor. Thus, if the predicted value of the acreage under the cultivation of a crop in 1941/42 is 1980 acres, the corresponding forecast figure 2100 acres and the other values remain the same as in the previous example the revised value is obtained as follows:

$$2277 = 2100 \left(\frac{1980 \times \frac{2300}{2000}}{2100} \right) \quad (6)$$

The procedures followed in the case of autumn rice, jute, sugarcane and sesamum are slightly different. As already pointed out the Agricultural Department published their own estimates of the acreage under autumn rice for 1944/45 and when comparison is made with findings of the Ishaque Report the statistics of the Agricultural Department are found to be considerably overestimated. On the other hand the predicted values are considerably lower. That the departmental figures up to 1940/41 are underestimates has also been shown by comparing these with the figures available from the Settlement Reports. In view of these considerations the revision factors for the period up to 1940/41 are obtained, as in the case of other crops, by dividing the findings of the Ishaque Report by the predicted values, despite the fact that the actual official estimates for 1944/45 are available. No revision is attempted in the case of acreage data for 1941/42 and 1942/43 as these are more or less similar to the product of the predicted values and the revision factors. On the other hand, the departmental estimates for 1943/44 and 1944/45 are similar and these have been brought down to the level of the findings of the Ishaque Report.

For jute it has been shown that the official estimates of production are always underestimated but the range of underestimation is not uniform over all the quinquennial periods (Table 1.13). Thus, the range of error is largest in the third quinquennium and this may be due to the fact that the departmental propaganda for the voluntary restriction of jute cultivation during the depression years was not as successful as was supposed. On the other hand this volume is smallest during the last five years when the acreage under jute cultivation was statutorily regulated. In view of these, no single revision factor has been used for the entire period. Instead, the quinquennial averages of acreage have been marked up on the basis of the discrepancy found between the official estimates of jute production and the 'actual' production as ascertained from trade statistics. It is clear that this procedure does not take care of the entire range of error in the acreage data because there is considerable overestimation in the figures on the yield per acre.

TABLE 1.13 *Estimated jute production compared with 'actuals'*

| Years | Estimated production as a percentage of 'actuals' |
|---------|---|
| 1920-24 | 79 |
| 1925-29 | 93 |
| 1931-35 | 75 |
| 1935-40 | 84 |
| 1941-45 | 91 |

In the case of sugarcane no significant upward movement is noticed in the acreage statistics from 1941/42 to 1944/45, for which departmental estimates are available. But there is one consideration which apparently makes it difficult to assume a uniform margin of error over the entire period. As the Great Depression set in, propaganda was launched for the extension of the acreage under sugarcane. This coincided with a sudden increase in the official estimate of sugarcane acreage beginning from 1931/32. This may raise doubt as to the reliability of the full increase thus shown. But there are at least two factors which make it reasonable to believe that there actually was some increase in the cultivation of this crop. These were the boosts given to the sugar industry by the grant of protection since 1928 and the distribution of an improved variety of seeds. For these reasons acreage under sugarcane has been uniformly deflated on the basis of the overestimation found by comparing the officially published data against the findings of the Ishaque Report.

A similar procedure is followed in the case of sesamum. This is due to the fact that the departmental estimates for 1944/45 are available. Secondly, in contrast with other crops, an upward movement in the acreage series is noticed from 1943/44. Acreage figures for sugarcane and sesamum for 1945/46 were not revised in the light of the data available from the Ishaque Report. These are, therefore, corrected on the assumption that the margin of error is the same as in 1944/45.

Data on the yield per acre of the different crops raise more complicated problems. This is because, as already pointed out, yield depends on a larger number of factors than does acreage under cultivation. The most important of these is rainfall. But yield does not depend only on the quantum of rainfall, but on its proper seasonal distribution. Secondly, the Department of Agriculture devoted most of its resources to the distribution of the improved variety of seeds evolved at the departmental experimental centres. It was claimed that these seeds could raise productivity by 25 per cent. By the late thirties almost the whole of the acreage under sugarcane and a considerable area under jute were being sown with these seeds. On the other hand, critics pointed out that the new seeds were tested only in the better soils and thus felt sceptical about the reliability of the yield differentials between the traditional and the new seeds as worked out by the Agricultural Department. These considerations make it very difficult to guess the variations in yield over the quinquennial periods. Ideally, a multiple regression with the known variables relating to yield might be attempted. But the volume of calculation which would be involved in working out the yield of thirteen crops grown in 27 districts over a period of 26 years is beyond the scope of the present work. Moreover, data are available only on rainfall and price and partly on the new seeds distributed. Further, independent estimates on yield are available for only three

crops – winter rice, autumn rice and jute. In view of these difficulties no independent revision of the official data on yield has been attempted. Instead, output of the crops have been revised on the same basis as in acreage statistics.

1.7 SOURCES OF DATA AND MINOR ADJUSTMENTS

All the statistics on the acreage under the cultivation of different crops and the areas designated as net cropped area, double cropped area, current fallow and cultivable waste are obtained from the *Season and Crop Reports*. Issued annually by the Government of Bengal Department of Agriculture, this was the basic publication on all agricultural statistics. The *Season and Crop Reports* were published immediately after the final forecasts and included figures available from these forecasts. Acreage statistics are available also from the *Agricultural Statistics of Bengal*, another annual publication of the Department of Agriculture. This was a later publication and the idea was to make available the crop statistics in their final form, i.e. after any revision made to the final forecast figures. But on inspection it is found that the data available from these two publications are identical except in only a few cases. Therefore, no adjustment has been made in the data collected from the *Season and Crop Reports*. The *Agricultural Statistics* also contained crop data available from the cadastral surveys (whether completed or in progress) and explanation for any major variation in the crop statistics of the current year from those of the preceding year. Data on the seasonal condition of the current yield per acre of the different crops are available only from the *Season and Crop Reports*. Figures on standard yields are obtained from the *Reports on the Results of the Quinquennial Crop-cutting Experiments*. These are available also from the *Estimates of Area and Yields of Principal Crops in India*. Data on standard yields for the last quinquennium are taken from the *Calcutta Gazette*.

In some cases, however, figures on condition factors were not published for particular districts. In such cases data available for the district in the previous year has been expressed as a percentage of the provincial average and this relationship has been assumed to hold good in the year for which such data were not published. In the case of barley no data either on standard yield or condition factor was published. Total output figures are, therefore, obtained from the *Estimates* and the yield per acre is assumed to be the same in all the districts where barley was grown. This procedure is followed also in the case of summer rice as no data on the condition factor and only some data on the standard yield were published. In the case of tobacco no data on the standard yield was published before the quinquennium beginning 1927/28. Yield per acre for these years (i.e. from 1920/21 to 1926/27) has been assumed to be the same for all the districts. Regional variations in the trend rates of the output

and yield per acre of tobacco have to be interpreted with reference to this limitation.

1.8 CLASSIFICATION OF CROPS

Crops could be classified in different ways. A division between food crops and non-food crops would place all the crops except tea, tobacco and jute in the former category. Therefore, such a classification does not seem to be meaningful. George Blyn divides crops between foodgrains and non-foodgrains. But this mode of classification is also defective as it describes crops such as sugar-cane, tobacco, jute and tea as grains. A classification between commercial and non-commercial crops would show whether market forces had a favourable impact on the output of certain crops. But the problem in such a categorisation is that except for tea and jute no crops are fully commercial or non-commercial. This is clear from the following estimates of the 'gross village retention' of the major crops of India.¹ Rice, 59%; wheat, 49%; barley, 71%; gram, 55%; sugarcane, 13%; tobacco, 7%; linseed, 20%; rape, mustard and sesamum, 5 to 10%.

Thus, it is clear that since a substantial portion of their output is sold in the market, it will not be desirable to categorise rice (in our case the three varieties of winter, autumn and summer rice), wheat, barley and gram as non-commercial crops. Therefore, in the present study these crops are grouped as food crops. As pointed out earlier, linseed, sesamum, rape and mustard, and sugar-cane should be categorised as food crops. But since only a small portion of the output of these crops was retained by the farmers, along with tea, tobacco and jute, these crops are classified as cash crops.

1.9 AGGREGATION OF CROP OUTPUT

For the purpose of aggregation, the physical volume of output of every crop is weighted by its price as these are the best indicators of the relative importance of particular crops. Prices are available both at the village and at the wholesale level. But for the present purpose, use is made of the harvest prices as these are supposed to be prices paid to the growers. The selection of base years, the prices of which would best reflect the relative importance of the different crops, does not seem to be very difficult. For obvious reasons the prices of the depression years and the famine years of 1940s cannot be used for the present purpose. Only the prices of the period from 1924 to 1929 may be regarded as normal.² Therefore, the averages of the prices of these years are used as weights.

¹ Blyn, *op. cit.*, p. 79.

² Bowley and Robertson, *op. cit.*, p. 44.

1.10 MEASUREMENT OF TREND RATES AND THEIR
PRESENTATION

The trend rates of both the revised and unrevised series are derived by fitting exponential equations of the type $\log y = a + bt$ over the entire period. This, however, does not indicate variations within the shorter segments of time. In order to obviate this difficulty the data on output, acreage and yield per acre have been converted into index numbers. These are presented as five quinquennial averages to facilitate comparison. These quinquennial divisions broadly correspond to the five periods which in themselves are well demarcated from each other by certain special features. Thus, the post-war recovery may be said to have started in the first period (1920–24) and this reaches its peak in the second (1925–29). The third period from 1930 to 1934 roughly corresponds to the depression years and the fourth (1935–39) to the years of relative recovery. Finally, the last period, from 1940 to 1944, witnesses the Bengal famine and the consequent steep increase in the price level. This is also the period when the upward movements in the acreage statistics are noticed. So the proposed procedure may be said to have the added advantage of focusing attention on the response of different crops to the changed circumstances.

Data on the three components of crop output are available for the districts (27 in all) in which such crops were grown. Since the purpose in the present study is not only to examine the trend rates of output, yield per acre and acreage under cultivation at the all-Bengal level, but also to give an idea about the regional variations within Bengal, the districts should ideally be taken as the regional units. But in view of the complexity and bulk of work such a procedure would involve this is not attempted. Instead, output and acreage under the cultivation of individual crops for all the districts under a Division have been added up and trend rates measured.¹ The rates of change, however, have to be interpreted with reference to the percentage distribution of the output and acreage of the different Divisions or Regions. Therefore these are presented in the respective tables.

Growth of population provides a useful criterion on which to judge whether the trend rates are low or high. Therefore, the percentage rates of change in output and acreage of food-crops, cash crops and all-crops are compared with the growth of population. Variations over the successive quinquennial periods are indicated by the change in the index of the ratios between population and crop output. Such a comparison is not, however, an entirely satisfactory procedure in view of the fact that per capita availability

¹ There are some discrepancies in the all-Bengal output figures calculated in this work and those published in the *Estimates of Area and Yields of Principal Crops in India, op. cit.*

depends not only on net crop output (total output – seed requirements, live-stock consumption, wastage, etc.), but also on net import (i.e. export – import). Therefore, an attempt has been made to estimate the per capita availability of foodgrains during the period under review.

2

TRENDS IN OUTPUT, ACREAGE AND YIELD: ALL-CROPS, FOOD CROPS AND CASH CROPS

In the preceding chapter it was shown that the officially published data on acreage under cultivation are mostly underestimates and those on yield per acre overestimates. Also discussed was how the revision of the official figures on acreage in the light of the data available from the Ishaque Report (1944/45) is likely to provide more reliable estimates of the agricultural trends in Bengal. The purpose of the present chapter is to analyse the percentage rates of change in crop output in the two series and their determinants – acreage and yield per acre. Trend rates of other provinces are also presented to indicate the comparative position of Bengal and, thus, to emphasise the greater rationality of the trends in the revised series. In order to bring out more clearly how the change in output, both at the provincial and regional level, was being influenced by the trends in acreage and yield, the three variables – output, acreage and yield – should be discussed simultaneously. But clearly such a mode of presentation would make the analysis more complicated than is desirable. Therefore, the percentage rates of change in the three items are presented separately. This is done first for all-Bengal and then individually for the five regions. The emphasis of the present chapter is on all the 13 crops taken together and then on the two groups of food crops and cash crops, though occasional references are made to some of the individual crops as well. In order to facilitate the interpretation of the differences in the percentage rates of change at the regional level the relative importance of these groups of crops in each region is also indicated. The analysis of the trends is followed by a discussion of the conceivable explanations for the contrast between the yields of food crops and cash crops.

2.1 ALL-BENGAL TRENDS IN ALL-CROP OUTPUT AND GROWTH OF POPULATION

Percentage rates of change in the production of all crops taken together are presented in Table 2.1 along with those of the other provinces of British India as estimated by Blyn.¹ During the period as a whole the provincial rate of

¹ George Blyn, *Agricultural Trends in India, 1891–1947: Output, Availability and Productivity* (University of Pennsylvania Press, 1966). Trend rates refer to the last four Reference Decades.

Bengal agriculture 1920–1946

1920–46

| Regions | Annual rates of increase | | | |
|------------------|--------------------------|----------------|------------|-------------------|
| | Unrevised series | Revised series | Population | % of total output |
| All-Bengal | 0.9 | 0.3 | 0.8 | 100 |
| Presidency | 2.0 | 1.1 | 1.2 | 15 |
| Burdwan | 0.0 | —1.0 | 0.8 | 14 |
| Rajshahi | 1.4 | 0.5 | 0.3 | 29 |
| Dacca | 0.8 | 0.4 | 0.9 | 31 |
| Chittagong | —0.2 | —0.7 | 1.3 | 12 |
| British India | 0.4 | | | |
| Madras | 0.4 | | | |
| Greater Bengal | —0.2 | | | |
| Punjab | 1.3 | | | |
| United Province | 0.3 | | | |
| Central Province | —0.6 | | | |
| Bombay-Sind | 0.8 | | | |

Note: Blyn's estimates are presented in the lower half of the table: see Blyn, *op. cit.*, p. 119.

increase was not only much higher than in any other province (except the Punjab) but it also exceeded the growth of population. However, the picture that emerges in the revised series is completely different. Bengal is left with the lowest rate of expansion in the sub-continent and as a result the disparity between crop production and the growth of population becomes very marked. However, it may be mentioned here that even after this downward adjustment the growth rate remains much higher than in 'Greater Bengal' as estimated by Blyn. This shows that the inclusion of Bihar and Orissa has considerably affected the rate of increase for Bengal proper.

As to the trends in the quinquennial periods (Table 2.2) two main features may be pointed out. The rate of increase gradually slowed down during the first 20 years and this was followed by some acceleration in the last five years. The turning point in this respect, as already pointed out, came in 1941/42 when the acreage data started to be revised by the Agricultural Department. This increase in the volume of output does not, however, reflect the entire range of upward revision of the acreage data as there was a considerable drop in yield per acre during these years. Secondly, it seems that the Great Depression did not have any adverse impact on the level of crop production in Bengal. The volume of production continued to increase despite a sharp fall

Trends: all-crops, food crops and cash crops

TABLE 2.2 *Index of all-crop output in the quinquennia*
(1920/21 to 1922/23 = 100)

| Regions | 1920-24 | 1925-29 | 1930-34 | 1935-39 | 1940-44 |
|------------|----------|----------|----------|----------|----------|
| All-Bengal | 98(98) | 104(100) | 109(105) | 113(109) | 120(101) |
| Presidency | 99(99) | 104(101) | 112(110) | 115(114) | 153(126) |
| Burdwan | 92(92) | 80(77) | 88(84) | 88(86) | 85(69) |
| Rajshahi | 100(100) | 114(107) | 123(116) | 125(117) | 136(108) |
| Dacca | 101(101) | 113(112) | 115(111) | 125(122) | 122(108) |
| Chittagong | 98(98) | 96(93) | 91(89) | 92(91) | 96(83) |

Note: Figures in the brackets refer to the revised series. No adjustment has been made in the output or acreage figures for winter rice and autumn rice before 1939-40 for the revision of the corresponding figures on jute. This would not make any significant difference as the weight of this latter crop was too small compared to the combined weight of these two varieties of rice.

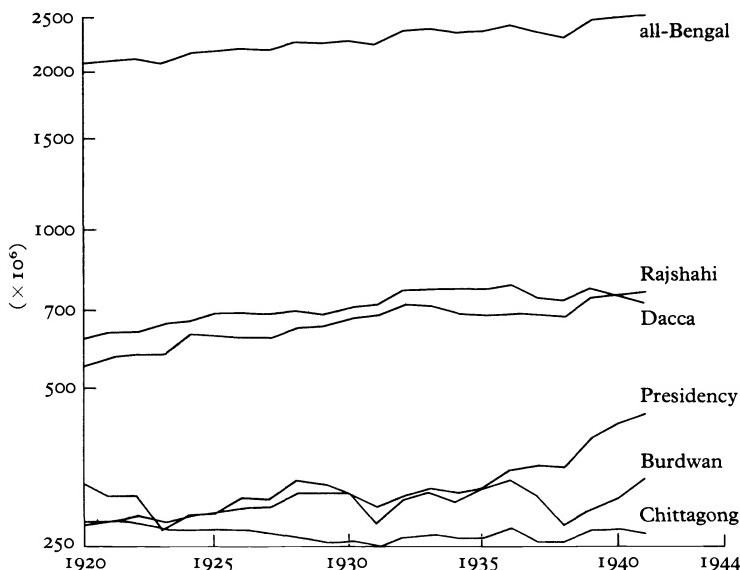

FIGURE 2.1 *All-crop output (official series), five years' moving average (log scale); output in arbitrary units, weighted by price)*

in the price level.¹ However, as shown later, this trend was not true to both of the two groups of crops. The revised series indicates a slight acceleration in the rate of expansion during the first 15 years and a slight drop in the fourth period. The trend is then reversed and as a result the volume of production during the last five years stands at about the level of the base period.

The trends of crop output per capita in the quinquennial periods reveal an important aspect of the agricultural economy of the province (Table 2.3). The volume of per capita crop production seems to have remained more or less constant, at the level of the base period, in all the successive quinquennia. Evidently this implies that the rate of growth in crop-production and population was the same for all the five periods. The same balance, though at a slightly lower level than in the base period, is noticed in the revised series up to the year 1939/40. Then, as expected, the balance is lost during the last five years when per capita all-crop output shows a decline of 15 per cent from the level of the base period.

2.2 REGIONAL ALL-CROP OUTPUT AND POPULATION GROWTH

The picture that emerges at the regional level is important as this shows that the provincial rate of expansion was representative of only one region – Dacca – which accounted for nearly one third of the all-crop production (Table 2.1). The four other regions belonged to two opposite extremes. Thus, in Rajshahi and Presidency Divisions the growth rate was considerably higher. But so far as the total picture is concerned these were almost wholly cancelled out by the stagnation in Burdwan and a slight decline in Chittagong. In the revised series the growth rate still remains higher in Presidency

TABLE 2.3 *Index of per capita all-crop output in the quinquennia
(1920/21 to 1922/23 = 100)*

| Regions | 1920–24 | 1925–29 | 1930–34 | 1935–39 | 1940–44 |
|------------|----------|----------|----------|----------|----------|
| All-Bengal | 98(98) | 100(96) | 100(96) | 100(96) | 101(85) |
| Presidency | 99(99) | 100(97) | 103(101) | 98(97) | 121(100) |
| Burdwan | 91(91) | 77(74) | 81(78) | 79(77) | 72(59) |
| Rajshahi | 100(100) | 112(105) | 119(112) | 119(112) | 126(100) |
| Dacca | 100(100) | 108(107) | 106(102) | 110(107) | 102(91) |
| Chittagong | 97(97) | 89(86) | 79(77) | 75(74) | 74(64) |

Note: Estimates based on the revised series are shown within brackets.

¹ This behaviour of the total volume of production during the depression years is explained in Chapter 4.

Division. But in Rajshahi and Dacca these rates are reduced respectively by one third and half. The most marked change, however, takes place in Chittagong and Burdwan, though in different directions. With regard to the relative growth of population and crop production it is clear that even in the revised series the position remains by far the best in Rajshahi and Presidency Divisions. An extreme case is presented by Burdwan which shows an annual decline of 1.0 per cent in crop production as against a growth of population at a rate of 0.8 per cent per year.

In Raishahi and Presidency Divisions the trends in all the successive quinquennia were the same as indicated by the provincial average. Dacca differed from this pattern only to the extent that there was a slight drop in output during the last five years. The two other regions had a negative trend in the second quinquennium. In Chittagong this drop continued up to the close of the depression period. This was followed by expansion at an increasingly higher rate during the last ten years. In the revised series the regional picture remains broadly the same as indicated by the provincial average. The only exceptions are noticed in the Presidency Division in the last quinquennium and Burdwan and Dacca in the third. Thus, to emphasise the trends of production during the depression years, at the regional level it is only in Dacca in the revised series and Chittagong in both series that output seems to have declined slightly.

As to the level of per capita crop production and its trend in the quinquennial periods the five regions fall under two groups. Thus, in Presidency and Rajshahi Divisions there was some improvement in food production during the first three and the last quinquennia. Dacca resembled Rajshahi in that crop production always exceeded the growth of population, though there was some drop in the third and the last quinquennia. The two other regions present a completely different picture. As already noted, fairly high rates of population growth were accompanied by stagnation and decline in crop production respectively in Burdwan and Chittagong and as a result the disparity became more and more marked. The position further deteriorates in the revised series, while in Rajshahi and Presidency Divisions crop output remained at the level of the base period.

2.3 ALL-BENGAL TRENDS IN FOOD CROP OUTPUT AND POPULATION GROWTH

Food crops accounted for 70 per cent of the total crop output and the average increase of 0.7 per cent per year (Table 2.4) considerably affected the trend in the latter. Changes effected by the revision of statistics are more marked when food crops are distinguished from cash crops. During the period as a whole

| Bombay-Sind | 0.4 | | | |

Source: For Blyn's estimates presented in the lower half of the Table see Blyn, *op. cit.*, p. 99.

food production remained stagnant as against an annual growth of 0.8 per cent in population. But, as in the case of all-crop production, this seems to be more in line with the experience in most of the other provinces. This strengthens the belief that, subject to the limitations of the yield figures, the revised series presents a more reliable picture of the agricultural trends of Bengal.

As to the quinquennial trends in the official series, it is only in the second period that food crop output slightly declined (Table 2.5). In the other quin-

TABLE 2.5 *Index of food crop output in the quinquennia

| Chittagong | 94 | 81 | 82 | 81 | 85(76) |

Note: Revised estimates are shown in brackets.

quennial periods the volume of production increased. But there were considerable differences in the rates of increase. Thus, while the rate of expansion of the output of food crops during the fourth quinquennium was marginal, it was somewhat marked in the third and the fifth quinquennia. These trends in the production of food crops during the first 15 years seem to have been mainly due to the shifts in the production of cash crops caused by changes in market conditions. As shown in Section 2.6, the production of commercial crops registered a sharp increase during the first decade, but it declined slightly during the depression years. The substitution between the two groups of crops seems to have come to an end during the fourth quinquennium.

The volume of output during the last five years for the first time exceeded the level of the base period. Although there was, thus, a seemingly general increase in production according to official statistics, Bengal was in the grip of a severe famine during these years. This apparent contradiction seems to have escaped the attention of the official compilers of statistics. The picture that emerges in the revised series is completely different. For the province as a whole foodcrop output during these years stands at a level which is 9 per cent lower than in the base period. Almost the whole of this drop is due to the reduction in the output of winter and autumn rice caused by the revision of statistics.

The disparity between the growth of population and food production started at the outset of the period under review (Table 2.6) and the gap continued to widen later on except for a marginal improvement during the depression years. The rate of decline was the most marked during the last five years when per capita food production reached a level which was 25 per cent lower than in the base period.

At this stage it will be quite legitimate to ask whether the decline in per capita food production really meant a drop in per capita availability. Evidently this question calls for an attempt to estimate the net quantity of food crops available for consumption, i.e. total output – seed requirements – waste –

TABLE 2.6 *Index of per capita food production in the quinquennia
(1920/21 to 1922/23 = 100)*

| Regions | 1920–24 | 1925–29 | 1930–34 | 1935–39 | 1940–44 |
|------------|---------|---------|---------|---------|---------|
| All-Bengal | 93 | 84 | 89 | 87 | 89(76) |
| Presidency | 96 | 89 | 97 | 91 | 110(92) |
| Burdwan | 91 | 75 | 79 | 78 | 71(58) |
| Rajshahi | 94 | 90 | 103 | 100 | 102(81) |
| Dacca | 94 | 89 | 91 | 94 | 92(86) |
| Chittagong | 93 | 75 | 71 | 66 | 65(58) |

Note: Figures in brackets refer to the revised series.

livestock consumption + imports. The proportion of paddy required for seeds may be estimated on the basis of the acreage under food crops. However, since our purpose is to estimate the trends rather than the actual quantity available per capita and since there was no significant expansion of acreage under cultivation, it may be assumed that this proportion remained more or less constant over time. The proportion of food crops wasted in storage and required for livestock consumption has been estimated by different organisations.¹ But it is not known whether this proportion increased during the period under review and, if so, to what extent. Therefore, no deduction from the total output is possible on these grounds. Thus, the issue that needs to be resolved is whether trade with foreign countries and other provinces made any significant change in the gross quantity of food crops available for per capita consumption.

Statistics on the trade in rice (as also gram, wheat and barley) with foreign countries and other Indian ports are available for the entire period. But the data on the trade through land frontiers with Assam, Bihar, Orissa and United Province are available only from 1925/26. On the other hand, no data is available on the trade by river and train. On the basis of these data it seems that during the 15 years from 1927/28 imports exceeded exports, but the net import amounted to only four per cent of the total domestic supply in the official series and three per cent in the revised series. During the last four years (1942/43–1945/46) there was a sudden drop in net imports, which amounted to less than one per cent of the total output.

According to the calculations of the Famine Enquiry Commission,² during the five years from 1927/28 exports exceeded imports, but net exports accounted for only 2.1 per cent of total output in the official series and 1.6 per cent in the revised series. During the next ten years (i.e. up to 1941/42) there was a net import of 1.1 million tons per year which amounted to only 1.4 per cent of the domestic supply in the official series and 1.1 per cent in the revised series.

Thus, though there are discrepancies in the details of the statistics available from the two sources, two points clearly emerge from them. Firstly, Bengal became a net importer of rice, at least from the beginning of the 1930s. Secondly, the quantity of net imports did not, however, constitute a significant proportion of the total available food crops. Rice was the most important food crop. Therefore, on the basis of the available data it may be safely concluded that net external supply did not significantly contribute towards narrowing the gap between the supply of foodgrains and the growth of population.

¹ See, for example, Food and Agricultural Organisation, *Destruction of Food in Storage by Insects, Mites, Rodents and Mold Fungi: Report of Expert Committee*, 1946.

² Famine Enquiry Commission, *Report on Bengal* (Calcutta, 1944).

Trends: all-crops, food crops and cash crops

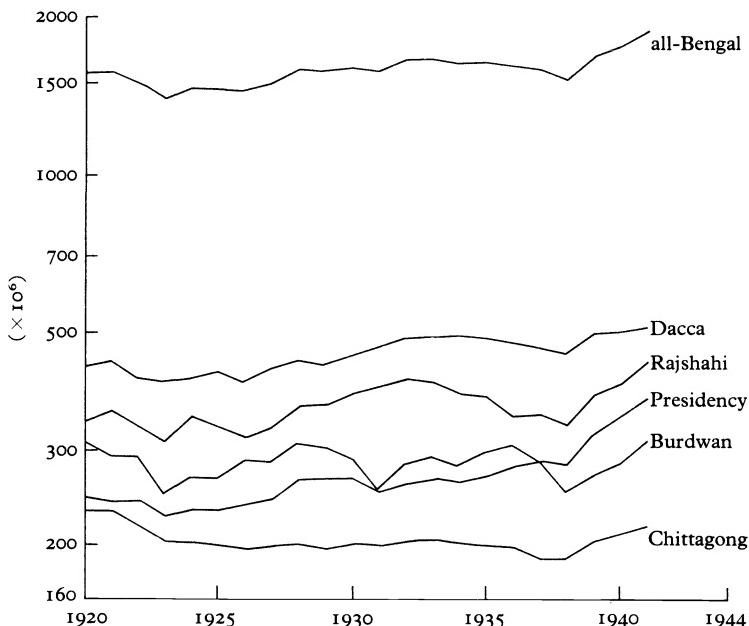

FIGURE 2.2 *Food crop output (official series), five years' moving average (log scale; output in arbitrary units, weighted by price).*

2.4 REGIONAL TRENDS IN FOOD CROP OUTPUT AND POPULATION GROWTH

At the regional level the provincial rate of increase of food crop output was representative of only Dacca Division (Table 2.4). Among the four other regions the rate was slightly higher in Rajshahi and much higher in Presidency Division. The annual rate of decline in Burdwan and Chittagong was not high, but as these two regions accounted for nearly one third of total food production this considerably depressed the provincial rate of expansion. The nature of change effected by the revision of statistics in the regional trend rates is more or less the same as in all-crop output and this is obviously due to the overwhelming importance of these crops in the total crop-mix. These variations in the trend rates of the different regions raise a number of important questions, but an attempt can best be made to explain them only after discussion of the two determinants of crop output – acreage and yield of individual crops. It may, however, be pointed out at this stage that these varia-

tions were not necessarily caused by the difference in the relative importance of these crops in each region.

In all the five regions the quinquennial trend up to 1934/35 was the same as indicated by the provincial average – a drop in the second period was followed by expansion in the third. It may, however, be pointed out that in Burdwan and Chittagong the drop was more marked than in the other regions. This similarity continued during the depression years when the index improved only marginally. During the post-depression years the five regions belonged to opposite extremes. In Chittagong and Dacca production declined slightly but in the other regions the improvement continued. This implies that the end of substitution between commercial and food crop output in this period indicated by the provincial average was representative of only three regions. In the revised series the drop in the index in Rajshahi and Burdwan is more marked than in the other regions.

At the regional level the unfavourable disparity between food production and population growth started, as indicated by the provincial average, at the beginning of the period under review (Table 2.6). But so far as the relative position in the subsequent quinquennia is concerned the three regions of Burdwan, Chittagong and Rajshahi merit particular attention as these belonged to opposite extremes. Thus in Rajshahi the disparity came to an end during the depression years. But, as expected from the high growth of population as against a decline in production, in Chittagong the disparity became more and more marked. The position in Burdwan was more or less the same except for the third quinquennium. To emphasise the level of per capita food production in the revised series it is clear that the all-Bengal picture during the last five years was not characteristic of any of the five regions.

A thorough investigation of the economic roots of the great famine of 1943 is outside the scope of this work.¹ However, some general comments may be made in the light of our findings on the trends in the per capita availability of food crops. On the basis of available data it has been shown that net imports constituted a small fraction of domestic output. Therefore, the stoppage of imports from other Indian ports and from Burma can not be said to have been an important factor behind the famine. At first sight this would suggest that the famine was caused by a decline in the level of domestic production. But a closer scrutiny suggests that this is not the whole truth. This is because even the decline in the per capita availability of food crops as indicated by the revised series does not fully explain the sharp rise in the price level during the last quinquennium. On the other hand, if we proceed on the basis of the

¹ The effects of the famine are examined by P. C. Mahalonobis, 'A Sample Survey of the After-Effects of the Bengal Famine of 1943', *Sankhya: Indian Journal of Statistics*, Vol. 7, Part 4 (1946); *Famine Commission Report, op. cit.*, Part 2, chapters one and two.

picture that emerges in the official series it seems that there should not have been any significant increase in prices.

The investigation of the Famine Enquiry Commission proceeded on the basis of a different set of data. But the Commission came to a similar conclusion regarding the causes of the famine. According to the findings of the Commission the supply situation in 1943 was worse than in any of the preceding years. This was attributed to two main factors: (*a*) a poor harvest of winter rice and (*b*) a shortage of rice stocks (because of the poor harvest in 1940/41). It was estimated that as a result of all these factors the total supply in 1943 was sufficient for 49 weeks.¹ However, it was asserted by the Commission that supply was not so bad as to make starvation on a large scale inevitable² – only a moderate increase in the price level would have been justified.

Thus, as concluded by the Famine Enquiry Commission, it seems that the main cause of the famine of 1943 has to be sought in the factors which affected the level of the demand for and the supply of rice in 1943. In other words, we should also take into account the series of inter-connected events which occurred at the end of 1942 and the beginning of 1943 and the impact of those events on all classes of people in the province – merchants, traders, producers, sellers and buyers of food crops.

The danger of large-scale Japanese attack led the military authorities of India to put into operation in 1942 a 'denial' policy which involved two measures of far-reaching consequences. Firstly, it was decided to take from the coastal districts of Midnapore, Bakerganj and Khulna the rice which was estimated to be in excess of local requirements. Secondly, the government decided to remove all boats (carrying 10 passengers or more) from those parts of Bengal which were considered vulnerable to Japanese attack.³ These measures brought home to the people the danger of invasion and created uncertainty and nervousness. This, in turn, produced an adverse impact on the level of the marketed surplus of rice and its demand. On the one hand, the prevailing fear and uncertainty probably encouraged the surplus producers to hold on to their grain as an insurance against worse days to come. Similarly, since the price was increasing the merchants and traders (as also many producers) are likely to have been encouraged to hold on to their stocks. On the other hand, it is very likely that the section of the people who depended on the market for

¹ *Famine Commission Report, op. cit.* p. 15. The Commission adjusted the figure by adding 20% to the figure given by the Director of Agriculture, See Appendix II, p. 215.

² One member of the Commission, Mr M. Afzal Hussain, believed that the shortage in total supply was the primary cause of the famine. He argued that for two thirds of the population 'so delicate was the balance between actual starvation and bare subsistence that the slightest tilting of the scale in the value and supply of food was enough to put it out of the reach of many and to bring large classes within the range of famine'. See *ibid.*, p. 16.

³ *Ibid.*, pp. 25–7.

the whole or a part of their requirements tried to buy more than their immediate requirements. The pressure of demand on the available supply was also increasing due to the fact that larger and larger numbers were being employed in industry and construction, refugees were flowing in from Burma and there was the demand for food for the army.

Thus the situation in Bengal in 1942 and 1943 was such that there was a shortage in the supply for food crops at a time when demand was increasing. Since the level of production was a little lower there would have been a slight reduction in the volume of the marketed surplus of rice. But the problem was aggravated by the dislocation of the normal channels of distribution of available supplies and a tendency on the part of the producers, consumers and traders to hoard food crops. The course of events during 1942 led them to believe that an ever-increasing rise in prices was inevitable and could not be prevented. The effect of the prevailing fear and uncertainty as well as the profit motive was that a little drop in the level of production had disproportionate consequences.¹ In view of the non-availability of reliable data it is very difficult to draw firm conclusions regarding the roots of the famine of 1943. However, if we proceed on the basis of available evidence it seems that the famine was 'more man-made than an act of god'.²

Before concluding this section it may be asked how, if people were at subsistence level in the past they multiplied at a fast rate while the per capita availability of food crops was declining. This raises the wider and much discussed question about the interrelationship between population growth and food production. According to the well-known view of Malthus and his followers population growth is the dependent variable, determined by preceding changes in agricultural productivity which, in turn, is the result of extraneous factors. The other extreme view on this question is that the main line of causality is in the opposite direction. Population growth is the independent variable which, in turn, is a major factor determining agricultural developments. According to this view population explosion is a change in basic conditions which must be regarded as autonomous – in the sense that its explanation should not be sought in increases in food production, but in medical inventions and other factors.³

Evidently the picture that emerges in this study on the trends in the per

¹ This was also the view of Sir T. Rutherford. For details see his memorandum to the Marqueses of Linlithgow in N. Mansergh (ed.), *The Transfer of Power 1942–7*, Vol. IV: *The Bengal Famine and the New Viceroyalty* (London, 1973), pp. 361–5.

² Opinion of the Bengal Congress Parliamentary Party cited by B. M. Bhatia, *Famines in India* (Bombay, 1963), p. 321.

³ A strong advocate of this view is E. Boserup. For details see his *The Conditions of Agricultural Growth* (London, 1965). For a general discussion on population theories see, UNO, *The Determinants and Consequences of Population Trends* (New York, 1973), Vol. I, Chapter III.

Trends: all-crops, food crops and cash crops

capita availability of food crops in Bengal conforms to this second view on the interrelationship between food production and population growth. It is beyond the scope of this work to pass any judgement on the validity of either of these two views. However, it is significant that the experience in Bengal was similar to that in other provinces of British India and some underdeveloped countries.¹ Thus, it becomes very difficult to dismiss the view that population growth is independent of the improvement in food production.

2.5 ALL-BENGAL TREND IN CASH CROP OUTPUT AND
POPULATION GROWTH

Trend rates in cash crop production present a very different picture (Table 2.7). For the period as a whole the rate of expansion was double the growth in population. However, as this group of crops accounted for only 30 per cent of

Source: For Blyn's estimates presented in the lower half of the table see Blyn, *op. cit.*, p. 112.

¹ During 1911-41 per capita food crop availability in British India declined by 26 or 0.83% per year. For details see Blyn, *op. cit.*, pp. 106-7. In Bangladesh per capita availability of food crops declined during the period from 1950/51 to 1962/63. For details see M. Alamgir and L. J. J. B. Berlage, 'Foodgrain (Rice and Wheat) Demand, Import and Price Policy for Bangladesh', *The Bangladesh Economic Review*, Vol. 1, No. 1 (1973) Table 1. See also, UNO *op. cit.*, Chapter XII.

the all-crop output this higher rate did not much improve the overall growth in food production. Secondly, the change effected by the revision of statistics is much less marked and as a result the contrast between the trends in the two groups of crops becomes more marked in the revised series. It is also significant that this rate of increase still remains higher than in British India or 'Greater Bengal'.

Two main observations may be made with regard to trends in the quinquennial periods (Table 2.8). The rate of expansion was accelerating during

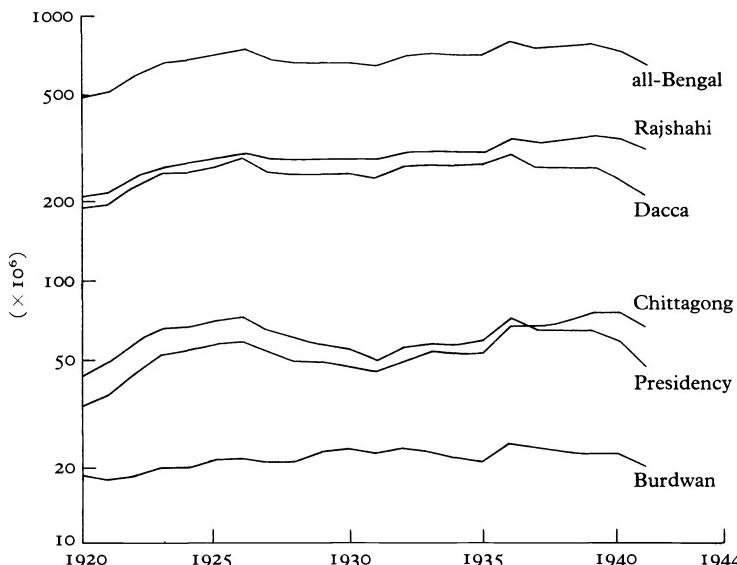

FIGURE 2.3 Cash crop output (official series), five years' moving average (log scale; output in arbitrary units, weighted by price).

Trends: all-crops, food crops and cash crops

the first 10 years and slowing down during the last ten. As already mentioned this drop in the rate of expansion was due to the end of substitution between food and cash crops. Secondly, as referred to earlier, changes in market conditions seem to have been the most important factor in determining the trends in the different quinquennia. Thus, it is clear that while there was a marked acceleration in production during the second period when prices were at their highest level before 1940, the depression years witnessed a considerable drop. Expansion started once again in the fourth period with the beginning of the post-depression recovery in prices. It may, however, be pointed out here that these shifts were mainly due to shifts in the production of jute, which was the most important crop in this category.

As anticipated from the preceding discussion, in sharp contrast to the change in per capita food crop output, per capita cash crop production

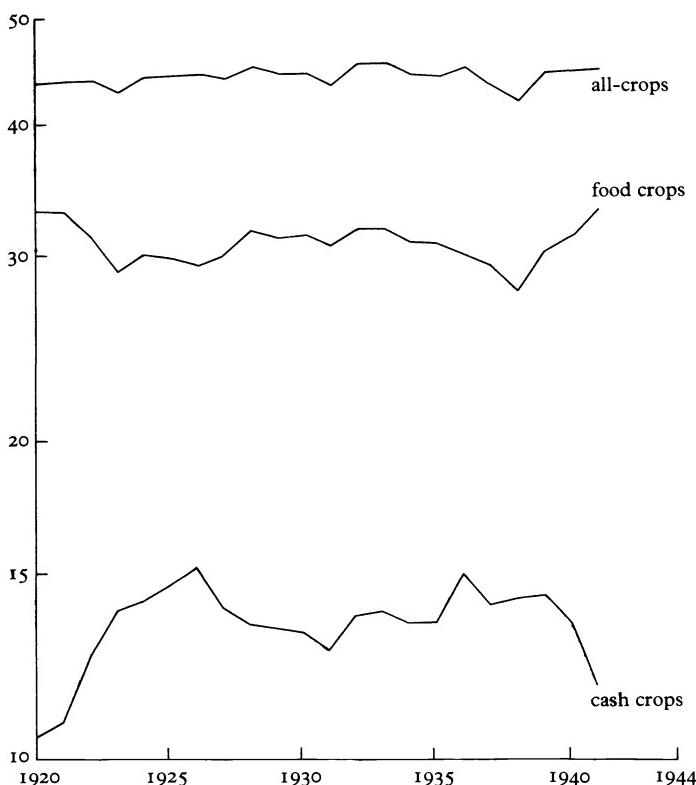

FIGURE 2.4 *Per capita crop production (official series, all-Bengal), five years' moving average (log scale; weighted by price).*

increased considerably during the period under review (Table 2.9). As to the rate of change, the five quinquennial periods fall into three unequal parts. During the first 10 years per capita output was improving at an increasing rate. This was followed by a marked drop during the third quinquennium. The fourth period witnessed some improvement, but the trend reversed again during the last five years.

2.6 REGIONAL TREND RATES IN CASH CROP OUTPUT AND POPULATION GROWTH

The rate of increase in the Presidency Division was double the provincial average. Conversely the growth rates in Dacca, Chittagong and Burdwan Divisions were much lower (Table 2.7). But it may be mentioned here that while in Burdwan and Dacca the rates were more or less the same as the growth of population, in Chittagong the disparity was marked. The picture that emerges in the revised series is more or less the same as indicated by the official series – the rates of expansion remain similar.

Except in Burdwan Division the quinquennial trends at the regional level were generally the same as indicated by the provincial average (Table 2.8). It is only in the last quinquennium that the trend was different in Dacca and Chittagong. On the other hand, in Burdwan Division the trend was the same as the provincial average only in the second and the last periods. In Dacca the drop in cash crop output during the last five years was caused by the fall in jute production. However, to emphasise the relative shift in production in response to changes in market conditions it is clear that the expansion of production in the second period was more marked in Presidency, Chittagong and Dacca Divisions than in the other regions. But the drop during the depression years was highest in Presidency and Chittagong Divisions.

The regional trends in per capita cash crop production in the quin-

Note: Estimates based on the revised series are shown in brackets.

Trends: all-crops, food crops and cash crops

quennial periods have two important features (Table 2.9). In sharp contrast to the change in per capita food production per capita cash crop output exceeded the growth of population in all the periods. The only exception was Burdwan. Secondly, the fact that for the province as a whole the rate of improvement was increasing during the first two quinquennia and declining during the last two was not true in all the regions: there was a drop in Dacca and Chittagong during the last five years.

2.7 PROVINCIAL TRENDS IN ALL-CROP ACREAGE AND THE SOURCES OF EXPANSION

The expansion of acreage under cultivation was the cause of almost the whole of the increase in all-crop output (Table 2.10). This is indicated by the almost identical growth for crop output (0.93) and crop acreage (0.87). Thus, during the period as a whole there was hardly any increase in yield per acre. In the revised series the annual rate of acreage expansion is reduced to nearly one fifth. However, it has to be pointed out here that this annual expansion of crop acreage at the rate of 0.2 per cent seems to be more in line with the experience in the other provinces. This, again, seems to strengthen

TABLE 2.10 *Trends in all-crop acreage*
1920-46

| Central Province | 0.1 | | | |
| Bombay-Sind | 0.4 | | | |

Note: For Blyn's estimates presented in the second half of the Table see Blyn, *op. cit.*, pp. 131-2.

the belief that the trend rates in the revised series provide a more accurate picture.

The trends in the quinquennial periods have two important features (Table 2.11). Firstly, they bring out an important point of difference between all-crop output and all-crop acreage. Thus, while during the first 20 years the rate of expansion was slightly slowing down in the former, it was increasing in the latter. The difference in the rate of increase (13 per cent in crop acreage and 6 per cent in crop output) during the last five years is of particular importance as this shows how a drop in yield per acre held down the volume of crop output during these years. Secondly, the fact that the depression did not have any positive impact on the level of crop output seems to be borne out by the expansion of acreage under cultivation during these years.

Expansion in crop acreage may be ascribed to three possible sources – transfer of land from other crops not included in this study, double cropping and finally cultivation of land classified in the official publications as ‘cultivable waste’, ‘current fallow’, ‘forest’ and ‘not available for cultivation’. The percentage rates of change in these categories of land together with those on net cropped area and total crop acreage are presented in Table 2.12. From this it is clear that during the period as a whole double cropping was the most important source of acreage expansion in Bengal. The annual average double cropped area increased from 44.7 million acres in the first half of the period to 57.0 million acres in the second. In the revised series the corresponding figures are 67.5 and 72.7 million acres. The next important source was the reduction in the proportion of land left fallow by cultivators for a year or two to recover its productive power. The area of land transferred from other crops and the expansion of cultivable waste were insignificant. In the revised series fallow and waste land show some increase. This may be due to the different method of classification used in the Ishaque Report and the official publica-

TABLE 2.11 *Index of all-crop acreage in the quinquennia

| Forest | | 0.2 | | | | |
| Total crop acreage | | (0.3) | | | | |

Note: Figures in brackets refer to the revised series.

tions. It is also possible that land transferred from the category of 'not available for cultivation' did not go directly into cultivation but was classified as cultivable waste and the land so transferred exceeded the area sown with crops. However, it is clear that the findings that double cropping and cultivation of fallow land were the two main sources of acreage expansion conform to what could be expected in a long-settled country with heavy pressure of population growth.

The areas of land classified under different categories in the quinquennial periods are presented in Table 2.13. These show how the changes in various classes of land influenced the trends in all-crop acreage in the different quinquennia. The rate of expansion in double cropped area was increasing during the first 15 years and slowing down during the last five. But in the case of fallow land it was only during the last 10 years that the extension of cultivation was taking place. This finding – the increase of fallow land during years of faster expansion in double cropping and slow decline when the rate of expansion in the latter was also small – may be of some significance. This may suggest that the cultivators were trying to make good at least a part of the loss in yield entailed by the increased double cropping by leaving more land fallow during the first three quinquennia. The decline in the area designated as 'not available for cultivation' may be regarded as more apparent than real.

TABLE 2.13 *Index of different classes of land in the quinquennia for all-Bengal (1920/21 to 1922/23 = 100)*

| Classes of land | Land as % of total | | | | |
|-------------------------------|--------------------|---------|---------|---------|----------|
| | crop acreage | 1920–24 | 1925–29 | 1930–34 | 1935–39 |

| Not cropped area | 83 | 99 | 98 | 99 | 102 |
| | | | | | 113(103) |

Source: Computed from data presented in the Appendix.

For it is reasonable to assume that in a long-settled country with rapid growth of population the area not available for cultivation would increase. But this seems to have escaped the notice of the compilers of statistics.

2.8 REGIONAL TRENDS IN ALL-CROP ACREAGE AND THE SOURCES OF EXPANSION

Among the five regions the annual rate of expansion of all-crop acreage in Dacca and Rajshahi was almost identical with that of the province as a whole (Table 2.10). The other regions were at opposite extremes. Once again, as in the case of all-crop output, in the official series the rate of expansion of acreage was the highest in Presidency Division. Conversely in Burdwan and Chittagong the rate was rather marginal. In Burdwan, Chittagong and Dacca there was some decline in yield per acre of all-crops and, therefore, the changes in the rates of expansion of all-crop acreage are less marked than those of production.

What were the sources of these changes in the all-crop acreage at the regional level? In both series the increase in double cropping was mainly responsible for the expansion of acreage under cultivation in Presidency and Dacca Divisions. Conversely in Rajshahi this was the most important source only in the revised series. In the official series the reduction in fallow land led to most of the increase in all-crop acreage. The decline in Chittagong and Burdwan was mainly due to the increase in fallow land. There was some expansion in double cropping, but the proportion of land double cropped was so insignificant that it could not offset the decline in all-crop acreage.

2.9 ALL-BENGAL TRENDS IN FOOD CROP ACREAGE

The average annual rate of expansion in food crop acreage during the period as a whole (Table 2.14) was almost identical with that of all-crop acreage (0.9 per cent). This is not, however, surprising in view of the fact that acreage under this group of crops accounted for more than 80 per cent of the total crop acreage. However, in the revised series the rate of expansion is much lower – only 0.2 per cent per year. It is once again significant that this is more in line with the experience in the other provinces.

The trends in the quinquennial periods confirm the pattern noticed in the food crop output (Table 2.15). There was a drop in acreage during the years of rising prices (1924–29) and expansion during the depression years. Once again the substitution between food crop and cash crops seems to have come to an end during the fourth period, and the turning point in this process was

the year 1935/36.¹ As pointed out earlier, the marked expansion of acreage during the last quinquennium was due to the upward revision of area under winter rice.

¹ According to K. Mukerji, at the all-India level this came to an end in 1927/28. See his, *Levels of Economic Activity and Public Expenditure in India* (Poona, 1965), p. 31.

Trends: all-crops, food crops and cash crops

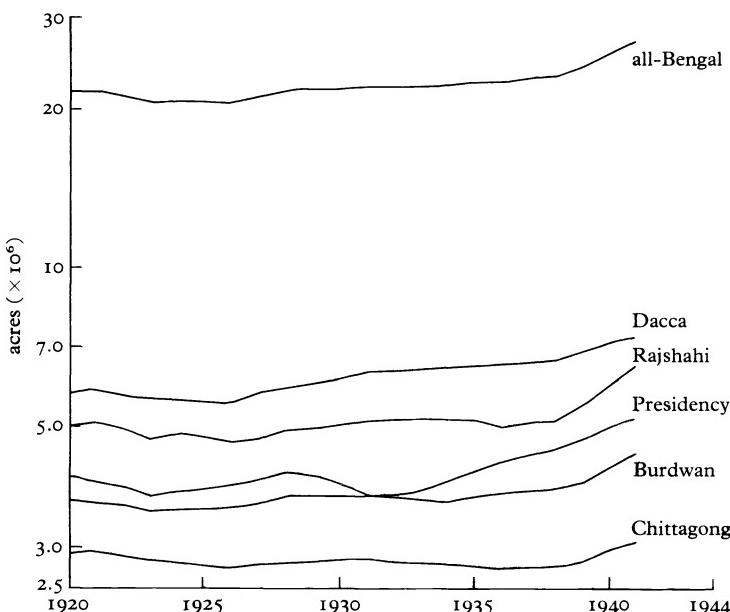

FIGURE 2.6 *Food crop acreage (official series), five years' moving average (log scale).*

2.10 REGIONAL TRENDS IN THE EXPANSION OF FOOD CROP ACREAGE

The picture presented by the trend rates at the regional level is more or less the same as indicated by the provincial average. In both the series the relative rates of acceleration or retardation in food crop acreage were similar (Table 2.14). The trends in the quinquennial periods also reveal the same pattern. It is only in Burdwan and Chittagong that there was a drop in the acreage under cultivation in the fourth period. This suggests that the substitution between food crops and cash crops was not yet over in these two regions. In the case of Chittagong this is particularly interesting in view of the fact that this region had the highest rate of population growth (1.3 per cent). Did the substitution come to an end during the last period? Nothing definite can be said about this, as the data on crop acreage was distorted by the upward revision. It may, however, be significant that, unlike in other regions, the revised series shows considerable expansion of acreage in these two regions.

2.II ALL-BENGAL RATES OF EXPANSION IN CASH CROP
ACREAGE

During the period as a whole cash crop acreage increased at the annual rate of only 0.2 per cent as against 1.0 per cent in food crop acreage (Table 2.16). In the revised series this comparative position considerably improves, though the rate of increase becomes very insignificant. It may be recalled here that the annual rate of increase in cash crop output was much higher than in food crop output. Obviously this has to be ascribed to the faster rate of increase in the yield per acre of this group of crops which will be noted later.

The same pattern which has been noted in cash crop output in response to changes in market forces is borne out, as in the case of food crops, by the quinquennial trends in the acreage under the cultivation of this group of crops – expansion during years of rising prices and contraction during years of falling prices (Table 2.17). However, it is clear that the drop in acreage in the depression period and the expansion in the last period was more marked than in output. This was due to the opposite movement in the figures on standard yield shown earlier in the course of the discussion on the quality of crop data.

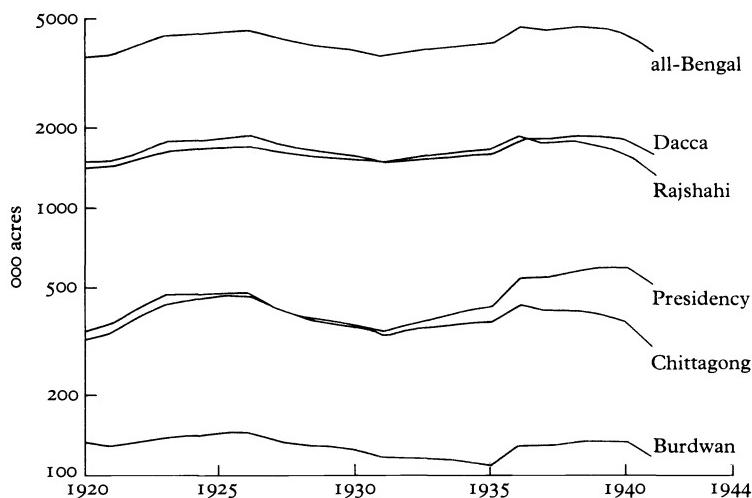

FIGURE 2.7 *Cash crop acreage (official series), five years' moving average (log scale).*

2.12. REGIONAL TREND RATES IN CASH CROP ACREAGE

The near-zero provincial rate of expansion in cash crop acreage was not typical of any of the regions (Table 2.16). In three regions – Burdwan, Dacca and Chittagong – acreage under cultivation declined during the period as a whole. (It may be recalled here that the rate of expansion in food crop acreage in Burdwan and Chittagong was the lowest.) In the two other regions cash crop acreage expanded and once again the average annual rate was the highest in Presidency Division. As indicated by the provincial average the picture that emerges in the revised series remains more or less the same.

This stands in sharp contrast to the marked changes effected in the trend rates of food crop acreage.

With regard to the trends in the quinquennial periods two main features may be pointed out. The general trend in the acreage under cultivation in the successive periods was the same as indicated in the provincial average. It is only in Burdwan in the fourth and Dacca in the last period that the trend was different. Secondly, though the general trend was the same the magnitude of change was considerably dissimilar. In this respect Burdwan and Presidency Divisions belonged to opposite extremes. Thus, while the rate of change was the most marked in the latter, it was the least so in the former.

2.13 PROVINCIAL TRENDS IN YIELD PER ACRE OF ALL CROPS

Increased agricultural output can be obtained either by the extension of the acreage under cultivation or by increasing the intensity of cultivation, or by raising yield or by combination of all three. It has been seen that during the period as a whole there was hardly any extension of cultivation. This is not, however, surprising in view of the fact that at the beginning of the period under investigation Bengal had the densest population in the sub-continent, and it is reasonable to believe that this pressure had already pushed cultivation almost to the natural limits. Under the circumstances increased production could be obtained only from intensive cultivation, i.e. raising yield per acre. The scope in this direction was very good as, at the beginning of this period, yield in Bengal was much lower than in the advanced agricultural countries.¹ But from the discussion that follows it is clear that at the end of the period the discrepancy remained as wide as before, and in some cases became wider.

Thus, during the period as a whole yield per acre for all the crops taken together increased at the rate of 0.1 per cent per year (Table 2.18). Clearly this implies that virtually the whole of the increase in all-crop output was obtained from the expansion of cultivation.

As pointed out later this rate was not typical of either of the groups of crops or of any individual crops. Does it imply that increase in the yield of one crop entailed decline in another? This question is discussed later on. But at this stage it may be pointed out that this near-zero trend in the productivity

¹ In spite of the considerable overestimation in yield as discussed earlier it is found that compared to Bengal at the beginning of our period the productivity of rice per acre was 260 per cent higher in Japan, 200 per cent higher in the USA and 300 per cent in Egypt. In the case of wheat it was 263 per cent higher in Japan, 284 per cent in the UK and 160 per cent in the USA. Even the productivity of a plantation crop like tea was 167 per cent higher in Japan. These estimates are based on figures available from the *Estimates of Area and Yields of Principal Crops in India* (annual).

per acre of all the crops seems to strengthen the opinion of the Royal Commission that a stable state had been reached in agriculture and no further decline was likely to take place in yield.¹ Increased yield involves the use of improved technology. But as there was hardly any progress in this direction the picture seems to conform to what could be expected for an underdeveloped agriculture — equilibrium at a low level of productivity.

However, in the quinquennial periods there were considerable variations in yield (Table 2.19). Thus, yield was increasing during the first 15 years, though gradually at a slower rate, and declined in the last quinquennium. So

TABLE 2.19 *Index of all-crop yield in the quinquennia*
(1920/21 to 1922/23 = 100)

| Regions | 1920-24 | 1925-29 | 1930-34 | 1935-39 | 1940-44 |
|------------|---------|---------|---------|---------|---------|
| All-Bengal | 99 | 104 | 107 | 107 | 101 |
| Presidency | 100 | 104 | 109 | 100 | 108 |
| Burdwan | 94 | 86 | 92 | 98 | 84 |
| Rajshahi | 102 | 115 | 123 | 121 | 114 |
| Dacca | 99 | 109 | 107 | 109 | 100 |
| Chittagong | 96 | 95 | 91 | 94 | 92 |

¹ Report of the Royal Commission on Agriculture in India (London, 1928), p. 76.

far as crop output is concerned this drop partly neutralised the effect of the upward revision in acreage data during the last five years. In this connection it may also be pointed out that the sudden increase in the standard yield for the quinquennium beginning 1932/33 did not have much effect on the yield per acre of all-crops as the 'annawari' estimates of the seasonal condition were lower during these years.

2.14 REGIONAL TRENDS IN YIELD PER ACRE OF ALL-CROPS

Among the five regions the trend in all-crop yield was positive in the Presidency and Rajshahi Divisions (Table 2.18). In the three other regions – Burdwan, Dacca and Chittagong – yield per acre declined during the period as a whole. This drop in yield in Burdwan and Chittagong Divisions is of particular significance as the revised series indicates that there was also a considerable decline in cropped area. However, in the Presidency and Rajshahi Divisions the rate of improvement in yield was higher than indicated by the provincial average. With regard to the quinquennial trends in Burdwan and Chittagong the decline in yield started at the outset. But while in the former there was some improvement during the third and the fourth periods, in the latter there was a slight rise only during the fourth. In the Presidency and Rajshahi Divisions improvement in the yield of all the 13 major crops taken together started at the beginning of the period under study and continued up to the third quinquennium. The fourth quinquennium witnessed some decline in yield in both these regions, but the trend was different in the last period.

2.15 PROVINCIAL TREND IN YIELD PER ACRE OF FOOD CROPS

For the period as a whole the average annual rate of decline in food crop yield was 0.2 per cent (Table 2.20). As acreage under food crops accounted for more than 80 per cent of the total acreage it is clearly this decline which depressed the rate of increase in all-crop productivity. The trends in the quinquennial periods indicate that this decline started at the outset and, except for a break during the third quinquennium, continued up to the end (Table 2.21). The drop in the yield per acre in food crops during the last quinquennium was wholly caused by the two lean years of 1940/41 and 1942/43 in the productivity of winter and autumn rice. The similarity of the level of yield per acre in the third and fourth periods merits particular mention. There was considerable decline in the standard yield estimated for the fourth period. But a run of favourable weather conditions seems to have kept the actual yield per acre at about the level of the first quinquennium.

2.16 REGIONAL TRENDS IN FOOD CROP PRODUCTIVITY

With regard to the trends in the yield of food crops the five regions may be said to have belonged to two groups. While in the Presidency and Rajshahi Divisions yield per acre remained more or less static throughout the entire period under review, in the three other regions the trend was one of decline (Table 2.20). It may be mentioned that except in Dacca these rates of decline (or of increase) are the same as for winter rice. As shown in the following chapter there was some rise in the yield of other food crops. But the share of winter rice in the total food crop acreage was so high (65 per cent) that these increases could make only a little difference.

The decline in the yield of food crops started at the beginning of the period under review (Table 2.21). In three regions – Burdwan, Chittagong and Dacca – this drop continued during the next five years. But in the two other regions there was an improvement. During the depression years yield increased in all regions except Dacca and Chittagong. In the next period there was improvement only in Burdwan, Dacca and Chittagong. The difference between the two neighbouring regions of Presidency and Burdwan was mainly caused by opposite trends in the yield of winter rice. During the last five years it was only in Presidency Division that there was some increase in productivity.

2.17 ALL-BENGAL TRENDS IN CASH CROP YIELD

Two main features may be pointed out with regard to the trends in the productivity of cash crops. In sharp contrast to a decline in the yield of food crops productivity in this group increased at the rate of 1.2 per cent per year (Table 2.22). This is particularly remarkable in view of the fact that productivity per acre of jute which accounted for more than 50 per cent of the non-food crops improved at the rate of only 0.3 per cent per year. Among

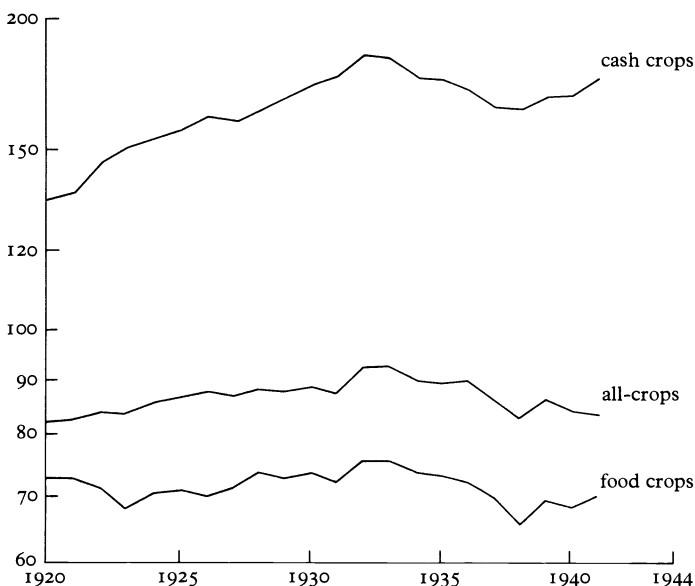

FIGURE 2.8 Yield of food crops, cash crops and all-crops (All-Bengal), five years' moving average (log scale; weighted by price).

Trends: all-crops, food crops and cash crops

TABLE 2.22 *Trends in cash crop yield per acre*
1920-46

| Punjab | 1.7 | |
| Greater Bengal | 0.8 | |
| United Province | 0.9 | |
| Central Province | -0.02 | |

Source: For Blyn's estimates presented in the lower half of the Table see Blyn's *op. cit.*, pp. 165-6.

other provinces with positive trends it was only in Bombay-Sind and the Punjab that the rate was higher.

Secondly, though the rate of increase for the period as a whole was impressive, it is clear from the quinquennial trends that the pace of improvement was slowing down during the first 20 years and this was followed by some decline during the last five (Table 2.23). But this drop was much less marked than in the productivity per acre of food crops. The only other period in which the trend in cash and food crop productivity was the same was the third quinquennium, but once again the rate of increase in the latter was much slower.

2.18 REGIONAL TRENDS IN CASH CROP YIELD PER ACRE

The average rates of improvement in productivity were almost identical with that of the all-Bengal average (Table 2.22). This stands in sharp contrast to the wide variations in the regional trends in the acreage under the cultivation of food crops and cash crops and partly in the yield of the former. In the course of the discussion on the trends in cash crop output it was pointed out that the variations in the rates of acceleration or retardation at the regional level do not seem to have necessarily depended on the relative importance of the particular group of crops in each region. This is brought

TABLE 2.23 *Index of yield of cash crops in the quinquennia*
(1920/21 to 1922/23 = 100)

| Regions | 1920-24 | 1925-29 | 1930-34 | 1935-39 | 1940-44 |
|------------|---------|---------|---------|---------|---------|
| All-Bengal | 106 | 123 | 136 | 138 | 133 |
| Presidency | 109 | 132 | 138 | 134 | 136 |
| Burdwan | 96 | 101 | 129 | 133 | 116 |
| Rajshahi | 105 | 122 | 135 | 136 | 136 |
| Dacca | 109 | 128 | 139 | 145 | 134 |
| Chittagong | 105 | 122 | 128 | 133 | 129 |

out more clearly by the opposite pattern in the two determinants of output—acreage and yield. The proportion of area under cash crops was the highest in Rajshahi and Dacca and the lowest in the Presidency and Burdwan Divisions. But these regions had opposite trends or widely dissimilar rates of increase or decrease in the area under cash crops. Conversely in the present case all the regions had almost identical rates of improvement in yield though the relative importance of the area under cash crop in each region was widely different.

The quinquennial trends reveal the same pattern as already noted for all-Bengal. The rate of increase in yield was slowing down during the period from 1920 to 1940 and this was followed by some drop in the last period. The only exceptions were Burdwan where the rate of improvement was accelerating during the first 10 years and Presidency Division which had some drop in yield in the fourth period as against some increase in the last. The drop in Presidency Division was almost entirely due to a marked decline in the productivity of jute.

In the previous chapter it was pointed out that it seems reasonable to assume that the trends in the revised series are more reliable. Now it is clear that this assumption is strengthened by the fact that the actual findings are more in conformity with the experience in the other parts of India. The picture of the agricultural economy of Bengal which is thus presented may be summarised as follows. Firstly, during the period as a whole there was hardly any increase in the yield of all-crops and only a marginal expansion of the acreage under cultivation. The resultant increase in all-crop output was much lower than the growth of population. Secondly, the experience between the two groups of crops was widely dissimilar. In the case of food crops a small increase in the acreage under cultivation (0.2 per cent per year) was neutralised by a corresponding decline in yield per acre. But in cash crops a still smaller increase in acreage (0.1 per cent per year) was accompanied by a fairly impressive improvement in yield per acre

(1.0 per cent per year). Thirdly, agricultural trends in the different regional units were considerably dissimilar.

This chapter may be concluded by an attempt to explain this contrast between the productivity of food crop and cash crops. What caused this difference? Once again this raises the question of the quality of the official data on yields considered in the preceding chapter. How far was this difference a real one? Obviously nothing definite can be said on this question. Therefore, the purpose here will be to see if there could be any conceivable explanation for this divergent experience as indicated by the official statistics. In this connection it may be recalled that of the individual crops responsible for the stagnation in the productivity of food crops the most important was the decline in the yield of winter rice. The yield of other food crops increased, but since winter rice alone accounted for 65 per cent of the total acreage under this group of crops the rates of increase could only neutralise the effect of this decline in winter rice. Thus, the question raised above is essentially a question as to the cause of the decline in the yield of winter rice as against an increase in that of cash crops.

One possibility referred to by Blyn is that jute and rice are alternative crops and the decline in rice yield was caused by the transfer of better land from the cultivation of rice to that of jute.¹ Another suggestion, made by Spate, is that jute and rice are associated in rotation planting and this might have caused the lowering of rice yield since jute is a soil-exhausting crop.² These explanations seem to be fairly convincing at first sight. But looked at more closely it seems that these suggestions do not fully explain the decline in rice yield.

Of the three varieties of rice it is only autumn rice which is a direct alternative to jute in the sense that these two crops are sown and harvested in the same season. In the case of winter rice its transplanting season coincides with the harvesting season of jute. After the jute harvest, planting of winter rice on the same land mainly depends on favourable weather conditions. Thus, winter rice is alternative only under favourable weather conditions. During the period as a whole the productivity of jute and autumn rice increased at the annual rate of 0.2 per cent and 0.3 per cent per year respectively. Now the questions that have to be asked are: if better land were transferred from the cultivation of rice, why did the productivity of autumn rice not decline? Secondly, why did the productivity of jute increase so marginally as against a much higher growth in the other cash crops. This is particularly important in view of the fact that by the late 1930s 50 per cent

¹ G. Blyn, *op. cit.*, p. 158.

² O. H. K. Spate, *India and Pakistan: A General and Regional Geography* (London, 1954), p. 527.

of the total acreage under jute was sown with improved seeds. In this connection it may also be mentioned that jute and winter rice accounted for respectively 9 per cent and 59 per cent of the total crop acreage. Clearly the impact of the transfer of better land should have been limited or even neutralised by the fact that 6 per cent of the rice acreage was sown with the improved varieties of seeds. Thus, it would appear that the decline in the yield of winter rice cannot be explained as mainly due to the transfer of better land or as due to rotation planting with jute.

A more important explanation may lie in the remarkable expansion of double cropping. It is reasonable to argue that most of this expansion took place on land under the cultivation of winter rice. This is suggested, firstly, by the importance of this crop in terms of acreage under cultivation. Secondly, the sowing and transplanting season of winter rice is such that it allows considerable scope for raising a second crop in the same agricultural year. It is well-known that different 'rabi' crops such as mustard, linseed, sesamum, gram are grown on land released by the harvest of winter rice. It is possible that there was an increase in the proportion of land transplanted with winter rice after the harvest of autumn rice and jute. It may be argued that the yield per acre of the crops so grown would also tend to decline. But there are reasons which suggest that this may not have happened. In the case of jute there was one upward force against the tendency for a drop in the yield resulting from double cropping. This was the use of the improved varieties of seeds. These seeds could not raise productivity by 25 per cent as was believed by the Agricultural Department, but it cannot be denied that they had some effect. Secondly, crops like wheat, barley, gram, sesamum, linseed and mustard accounted for only 8 per cent of the total acreage under cultivation. It is conceivable that the small size of the area under cultivation enabled the cultivators to take greater care of manuring, ploughing and weeding. This possibility is particularly applicable in the case of tobacco and sugarcane. In this connection it may also be mentioned that improved seedlings were used for these two crops. By the late 1930s more than half of the acreage under the latter was planted with the new varieties of seedlings.

Thus, the explanation for the contrast in the yields of these two varieties of crops as indicated by the official data seems to lie in the effect of the transfer of better lands from winter rice, the extension of double cropping, the use of improved varieties of seeds and perhaps the greater care in the cultivation of certain cash crops.

The variations which have been pointed out at the regional level with regard to the trends in acreage under cultivation and yield per acre raise a number of important questions. This is particularly so in view of the fact that the two neighbouring regions of Burdwan and Presidency Division had

Trends: all-crops, food crops and cash crops

such divergent experience. But these can best be appreciated with reference to the trends in the individual crops which are taken up in the next chapter. At this stage it need only be recalled that these variations do not seem to have necessarily been due to the difference in the relative importance of the two groups of crops in each region.

3

TRENDS IN OUTPUT, ACREAGE AND YIELD: INDIVIDUAL CROPS

Percentage rates of change presented in the preceding chapter reveal the picture of a stagnant agricultural economy characterised by the near-constancy of both acreage under cultivation and yield at the aggregate level. In the present chapter the analysis is taken a step further by examining whether this picture was representative of all the individual crops. There are several questions that need resolving. For example, if the trends were dissimilar, what was the significance of this difference? Again, it is imperative to seek some possible explanations for these dissimilarities. The mode of presentation is more or less the same as in the previous chapter. In the discussion on the quinquennial trends the emphasis is on the provincial average. In order to facilitate the interpretation of the rates of change in the 13 crops selected for analysis their weights in the all-crops acreage and all-crop output at the all-Bengal level are shown in the respective tables. The analysis of the changes is followed by an attempt to explain the differences in regional trends.

3.1 PROVINCIAL AND REGIONAL RATES OF CHANGE IN THE CROP OUTPUT

Considerable variations are noticed in the trends of the output of individual crops (Table 3.1). In both series the annual rates of growth were highest for sugarcane and gram. In the case of the former this has to be attributed to the introduction of a protective tariff against the import of sugar and the consequent expansion of local manufacture.¹ The remarkable expansion in the output of gram started in the middle of the 1930s despite the fact that exports of this crop had been declining since the beginning of the period under review.² This would thus indicate, at least partly, a tendency towards in-

¹ The number of sugar mills in Bengal increased from only two in 1933 to nine in 1939 with a daily crushing capacity of nearly 4000 tons. For details, see, Government of India, *Report on the Marketing of Sugar in India* (Delhi, 1939), p. 12. Working in the same direction was the introduction of the improved varieties of seedlings as discussed in the preceding chapter.

² All the export figures are available from the *Annual Statement of the Sea-Borne Trade and Navigation of British India*, published by the Director General of Commercial Intelligence and Statistics, Government of India, Delhi (annual).

1920-46*

| Crops | Relative importance | All-Bengal | Presidency | Burdwan | Rajshahi | Dacca | Chittagong |
|-------------|---------------------|---------------|---------------|----------------|--------------|----------------|----------------|
| Winter rice | 53 | 0.4 (-0.3) | 1.7 (0.8) | -0.1 (-1.2) | 0.6 (0.3) | 0.1 (-0.2) | -0.4 (-0.6) |
| Autumn rice | 15 | 1.6 (0.9) | 1.6 (0.8) | 0.4 (1.4) | 2.0 (0.5) | 2.8 (2.7) | -0.2 (-1.7) |
| Jute | 17 | 0.7 (0.2) | 2.4 (2.0) | 2.0 (1.7) | 1.2 (0.7) | 0.0 (-0.4) | 0.3 (-0.1) |
| Mustard | 1 | 0.1 (0.3) | 3.1 (3.3) | 0.3 (1.1) | 0.5 (0.6) | -0.8 (-0.5) | 0.1 (0.2) |
| Summer rice | 2 | 1.8 (1.0) | 3.4 (2.2) | 0.5 (-3.3) | 2.3 (1.2) | 1.8 (1.5) | 0.1 (2.7) |
| Gram | 1 | 6.6 (5.0) | 7.8 (6.5) | 2.6 (0.6) | 5.4 (3.3) | 3.6 (1.2) | 3.1 (0.0) |
| Wheat | 1 | 2.6 (2.3) | 4.6 (4.6) | 2.4 (0.7) | 1.1 (1.1) | 3.8 (3.3) | - |
| Sesamum | 1 | 1.5 (1.5) | 3.9 (3.9) | -0.6 (-0.6) | 1.8 (1.8) | 1.2 (1.2) | 2.9 (2.9) |
| Tobacco | 2 | 0.7 (1.9) | 0.3 (-0.7) | -2.2 (-0.6) | 0.1 (1.8) | 3.4 (3.3) | 2.4 (2.0) |
| Linseed | 0 | 2.1 (2.1) | 4.3 (4.3) | -0.6 (-0.6) | 0.3 (0.3) | -1.5 (-1.5) | 1.0 (1.0) |
| Sugarcane | 4 | 4.3 (4.3) | 7.1 (7.1) | 0.1 (0.1) | 4.3 (4.3) | 5.6 (5.6) | 1.4 (1.4) |
| Tea | 4 | 2.9 | - | - | 2.9 | - | 1.1 |
| Barley | 0 | 2.8 (1.1) | 5.3 (4.7) | -2.6 (-3.0) | 3.2 (0.1) | 1.4 (0.7) | - |
| All-crops | 100 | 0.9 (0.3) | 2.0 (1.1) | 0.0 (-1.0) | 1.4 (0.5) | 0.8 (0.4) | -0.2 (-0.7) |

Note: Figures in brackets in this table refer to the revised series. Differences in the relative importance in the two series are not marked and therefore only the weights in the official series are presented.

creased consumption of the inferior foodcrops. Conversely, the rates of increase in the official series were the lowest for mustard, winter rice, jute and tobacco. The revised series reveals a completely different picture for winter rice. This crop accounted for more than half of the total crop output in Bengal and evidently this decline of 0.3 per cent per year was of the greatest importance for the economy at large. Jute was the most important of the cash crops, but the revised series indicates a very much lower rate of increase. As almost the whole of the jute production was exported, either in raw or manufactured form, this may indicate the effects of the restrictive

practices of the local manufacturers,¹ the drastic fall in world consumption during the depression years and the increased needs of food production beginning from the middle of the 1930s. The very low rate of increase in mustard could have been due to the gradual decline of the export trade in this crop from the outset of the period. Autumn rice and summer rice belonged to one group and, in sharp contrast to the experience in winter rice, output of these two crops was increasing considerably. In both the series the trends were much better for crops like barley, wheat, sesamum, linseed and tea which together accounted for only 6 per cent of the all-crop output. Thus, it was the output of only the minor crops which was increasing during the period as a whole and evidently the rates were much higher than those indicated by the weighted average of all the crops.

For almost all the crops the provincial rate of change was not representative of any of the five regions. Presidency Division formed a category by itself in that the annual rates of increase were the highest in all the individual crops except autumn rice and tobacco. Burdwan and Chittagong belonged to the extreme opposites in almost all the crops. Of particular importance in the latter was the marked decline in winter rice and autumn rice. In Burdwan the drop in winter rice was marginal and there was some improvement in autumn rice, gram and wheat. But these were offset by the very high rates of decline in barley and tobacco. The contrast between these three regions becomes more marked in the revised series. In the former the rates of increase still remain impressive and in many cases as high as in the official series. But in Burdwan and Chittagong the position further deteriorates. In both the series Dacca and Rajshahi occupy a somewhat middle position. They had the same trend in almost all the crops though the rates of change were different.

3.2 PROVINCIAL AND REGIONAL TRENDS IN THE QUINQUENNIAL PERIODS

For the province as a whole the level of output of nine crops was lower during the first five years than in the base period (Table 3.2.). Among the remaining crops production of tea and jute was increasing, though at low rates. Thus, it was only on the production of these two crops that the post-war recovery in the market conditions was beginning to have some effect.² This provincial picture in the first quinquennium was typical of all the regions

¹ See *Report of the Bengal Jute Enquiry Committee*, Vol. I (Calcutta, 1939), p. 22.

² The supply response of the major crops for the period as a whole is examined in a separate chapter. The purpose in the present chapter is to emphasise, in a straightforward way, the pattern of shifts in the quinquennial periods.

Trends: individual crops

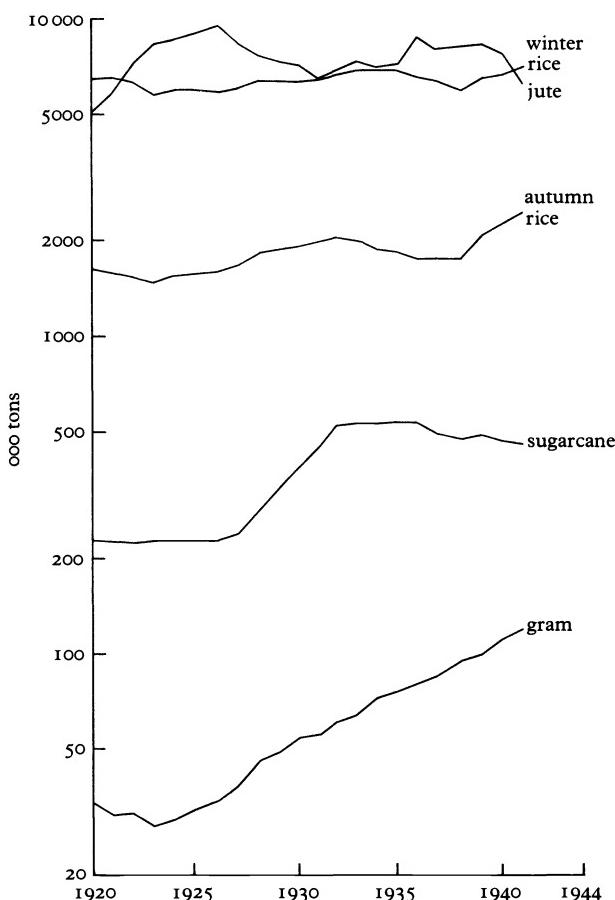

FIGURE 3.1 *Individual crop output (official series, all-Bengal), five years' moving average (log scale).*

in most of the crops including winter rice and autumn rice. The most marked exception was the drop in jute production in Burdwan.

For the province as a whole the trends in the output of the 13 crops were slightly different in the second quinquennium (Table 3.3) when prices were at their highest level. Apart from jute and tea the output of linseed and tobacco also responded to these favourable market conditions. However, the pattern of the last two crops was not the same in all the regions. This was true also with regard to the crops with negative trends during these

Trends: individual crops

years. For example, in Dacca and Rajshahi output of raw sugar increased as against a decline in linseed. Among the three crops with a positive trend the highest acceleration took place in jute production. Conversely, the decline in output was the most marked in winter rice and the least so in autumn rice. This clearly suggests that the expansion in jute production in this quinquennium was mostly at the cost of winter rice.

The picture completely changed during the depression years. Of the several crops which had responded positively to the rise in price level in the past, now it was only the production of jute which dropped with the fall in prices (Table 3.4). It may, however, be of significance that the rate of decline was much less than the rate of increase in the preceding quinquennium. Output of tobacco, linseed and tea continued to increase though there was a considerable fall in prices. The increase in the production of tea as against a drop in jute is important as it underlines how, in the absence of an alternative product, the highly capitalised estates could not adjust their production to the fall in the price level.¹

Similarly, the output of other crops, including winter rice and autumn

| | (105) | (110) | (84) | (116) | (111) | (89) |

Note: Estimates based on the revised series are presented in brackets.

¹ This was also the experience in Malaya and the Dutch East Indies. See P. T. Bauer, *The Rubber Industry* (London 1948), p. 30.

rice (which declined in the earlier years in contrast with the increase in jute production), improved considerably during these years. The sudden spurt in the production of sugar reflects the timing of the introduction of the protective tariff and the consequent beginning in the expansion of domestic industry. Thus, the finding of the preceding chapter that there was an upward shift in all-crop output during the depression years was also characteristic of all the individual crops. The only exception was jute — a fully marketed crop. Trends at the regional level were almost uniformly the same as indicated by this provincial average. In this respect, also, the experience in the third quinquennium was different. This may suggest that the effect of falling prices is more pervasive than that of rising ones.

During the post-depression years there was a considerable improvement in market conditions. But the recovery in jute production, even in the revised series, was small (Table 3.5). The output of other crops, including winter rice, continued to increase. Since there were two lean years in the yield of autumn rice — the other alternative crop to jute — and this held down output despite some expansion of acreage it may be suggested that the trend was much the same as for other crops. This was in sharp contrast to the experience in the first and second quinquennia. This new pattern is of considerable importance as it indicates that the increased needs of food supply

Trends: individual crops

curtailed the production of jute and expanded that of rice. It is true that the recovery in the price level was slow to come, but the underlying trend is fairly clear.

As pointed out in the discussion on the nature of the official statistics there was a sudden acceleration in the output of all the crops except mustard, tea, tobacco and sugarcane during the last five years (Table 3.6). Clearly the difference between food crops and cash crops has to be attributed to the 'Grow More Food Campaign' launched during these years by the provincial government. Consequently, the changes effected by the revision of statistics are more marked in these crops. The sharpest drop takes place in winter rice and output stands at a considerably lower level than in the base period. In the context of the Bengal famine of 1943 this seems to have been of the greatest importance. Autumn rice still shows some increase along with the two marginal crops of gram and barley.

TABLE 3.6 *Index of output 1940-44*
(1920/21 to 1922/23 = 100)

| Crops | All-Bengal | Presidency | Burdwan | Rajshahi | Dacca | Chittagong |

| Sugarcane | 197 | 302 | 82 | 212 | 258 | 109 |
| Tea | 197 | - | - | 199 | - | 120 |
| Barley | 164 (120) | 270 (244) | 57 (52) | 165 (89) | 136 (121) | - |
| All-crops | 120 (101) | 153 (126) | 85 (69) | 136 (108) | 122 (108) | 96 (93) |

Note: Revised estimates are presented in brackets.

The regional picture once again brings out the contrast between Presidency Division on the one hand and Burdwan and Chittagong on the other. While for the former even the revised series shows some increase in the output of all the crops the trend is the opposite for the latter two regions.

3.3 PROVINCIAL AND REGIONAL TRENDS IN ACREAGE UNDER CULTIVATION

With regard to trends in acreage the 13 crops may be classified under several groups (Table 3.7). In both the series the rate of expansion was the highest in gram. However, this expansion of acreage was accompanied by only a marginal improvement in yield. Acreage under the three crops of sugarcane,

Trends: individual crops

barley and wheat also increased at high rates, but together these crops accounted for only two per cent of the total cropped area. Among the other minor crops the trends were one of some expansion in tea, sesamum and linseed and some decline in mustard and tobacco in the official series. The high rates of expansion of acreage under barley and wheat, despite the fact that yield per acre in Bengal was one of the lowest in the sub-continent, underlines, as in the case of gram, the increased necessity of raising a second food crop in the dry season, though this generally meant the consumption of inferior cereals. The slow rate of expansion of the acreage under tea, even though productivity was increasing at 2.3 per cent per year, could have been due to the limited scope for the extension of tea plantation in undivided Bengal. According to the official series acreage under the two major crops of winter and autumn rice increased and in the latter the rate of expansion was double the rate of population growth. Area under autumn rice has a positive trend also in the revised series, but in winter rice the picture is one of stagnation. Clearly this stagnation was responsible for the near-zero trend in all-crop acreage.

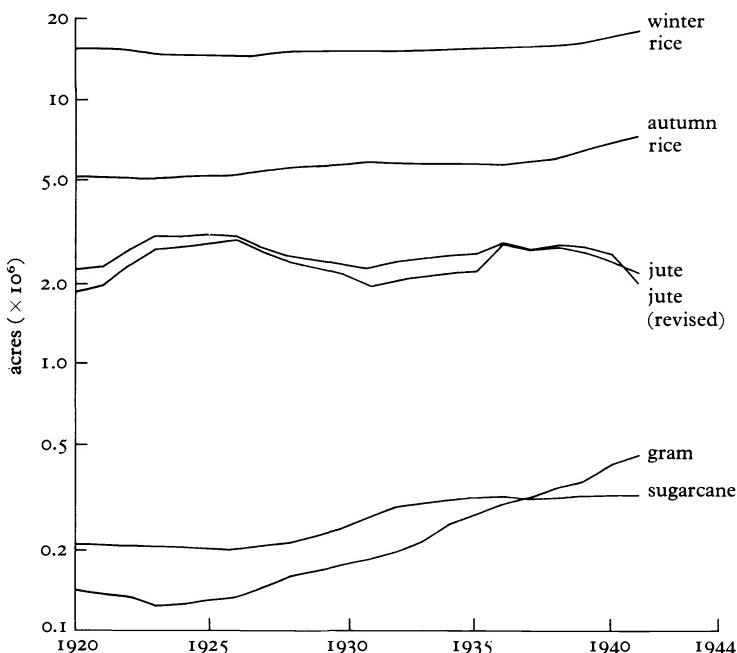

FIGURE 3.2 *Individual crop acreage (official series, all-Bengal), five years' moving average (long scale).*

The regional trends reveal the same pattern as noticed in the case of output – the all-Bengal average rates were not representative of most of the component units. On the contrary, the contrast between Presidency Division and the two regions of Burdwan and Chittagong was more marked in crops like sesamum, linseed and tobacco. Obviously this was due to the similarity of the trends in the yield of these crops as shown in the relevant section. The problem of discerning the possible explanations for the variations in the trends of the individual crop acreage at the regional level is discussed at the end of this chapter. But at this stage it may be pointed out that the pattern in the individual crop confirms the finding of the previous chapter that the rates of change in a crop did not necessarily depend on its relative importance in each region. Thus, for example, while the relative importance of autumn rice was more or less the same in Rajshahi and Dacca the rates of change in both the series were completely different. Again, Presidency and Burdwan Divisions accounted for one fifth and one sixth respectively of the total acreage under winter rice. But while the rate of expansion was 1.6 per cent in the former it was only 0.2 per cent per year in the latter.

3.4 PROVINCIAL AND REGIONAL TRENDS IN THE QUINQUENNIAL PERIODS

The quinquennial trends in acreage under the cultivation of individual crops were in general similar to those in output. Thus, during the first five years it was only in the case of the two minor crops of linseed and wheat that the trends were different from those in output (Table 3.8). Otherwise the general pattern was the same – the acreage under tea and jute was expanding with the recovery in the market conditions and this was accompanied by a decline in the acreage under the remaining crops. It may, however, be pointed out that the rate of expansion of the acreage under jute and the rates of decline in the other crops were slower than for output. Secondly, at the level of the regional units the variations were more marked.

The trends in the second period were more or less similar. As market conditions continued to improve, the acreage under the cultivation of jute, tobacco and tea expanded and this was accompanied by some decline in the other crops (Table 3.9). It is, again, important that the rates of decline, particularly in winter rice, were not as high as in output. Conversely, in jute and tobacco the pace of expansion was slower. This indicates that yield per acre was perhaps an important factor in the magnitude of response of the various crops to the changes in the price level. Thus, while a drop in the productivity of autumn rice was accompanied by some expansion of acreage

during these years the pattern was just the opposite for linseed. So far as the regional picture is concerned these provincial trends were most representative in the case of winter rice, gram and jute. In the other crops there were considerable variations.

During the depression years the acreage under cultivation expanded for all the crops except tobacco, linseed and jute (Table 3.10). It may be recalled here that with regard to output it was only in the case of jute that the impact of the depression was felt. However, since the decline in the acreage under linseed and tobacco was so marginal it may be suggested that the nature of the impact of the depression on the acreage under the cultivation of individual crops was similar to that on output. The provincial pattern was most representative of the regional trends once again in the case of winter rice, autumn rice, wheat, barley, gram and jute.

The expansion of acreage under all the individual crops during the period from 1935 to 1939 confirms the earlier findings on the end of substitution between jute and the two varieties of rice; and, secondly, confirms the increased emphasis on minor cash crops (mustard, linseed, sesamum and tobacco) for cash needs (Table 3.11). There was a considerable increase also of acreage under wheat, barley and gram. This increase in the cultivation of

these minor crops clearly reflects the expansion of the double cropped area which took place during these years. For these crops are grown during the interval between the harvesting and sowing of the major crops – winter rice, autumn rice and jute. Another feature of the trends in this quinquennium is that even in the case of these crops the rates of increase were higher for food crops. This would again indicate the emphasis on increased food production.

The trends in the last quinquennium bring out more clearly the effects of the upward revision of statistics during these years (Table 3.12). For reasons already referred to, the rates of increase were highest for the food crops. Acreage under the other crops remained either stagnant or increased at a slower pace. With regard to the rates of acceleration among the individual food crops the expansion of acreage under minor crops like wheat, barley and gram was much higher.

As to the effects of the revision of statistics, winter rice and jute fall under one group in that the trend is reversed. The near-zero trend in autumn rice during these years has to be interpreted with reference to the relatively simple method of revision. Thus, it is only in the case of minor crops that the revised series indicates some expansion of acreage.

3.5 ALL-BENGAL AND REGIONAL RATES OF CHANGE IN YIELD PER ACRE

The near-zero trend in the yield of all the crops taken together may be said to be most representative of autumn rice, which accounted for one fifth of the total acreage under cultivation (Table 3.13). The annual rates of increase of the most important cash crop (jute) and the three minor food crops of gram, wheat and barley were better, but still low. In the case of the last three crops this, however, conforms to what could be expected, as the climatic conditions of Bengal are less suitable for the cultivation of these crops than other parts of India. With a moderate annual growth of 0.7 per cent, mustard and summer rice belonged to one group followed by linseed, tobacco and sesamum in another. The trends in these three crops were fairly high but their combined relative importance was small. The three other crops belong

to two opposite extremes. Thus, the productivity per acre of sugarcane and tea increased at the rates of 1.8 per cent and 2.3 per cent respectively per year. Conversely the yield of winter rice declined at the annual rate of 0.3 per cent. As pointed out in the previous chapter this was of the greatest importance for the agricultural economy at large and may perhaps explain at least a part of the much better trends of some of the minor crops. Thus, generally, the trends in yield per acre reveal the same pattern – productivity increased only for the minor crops.

At the regional level the rates of increase of the yield of linseed, tobacco, sesamum and the rates of decline in gram were more or less the same in all the component regions. In the case of the other crops there were considerable variations – most markedly for winter rice. Thus, while the trend in the Presidency Division was still positive, the rates of decline varied from 0.1 per cent in Rajshahi to as high as 0.8 per cent in Chittagong. Rajshahi and Dacca accounted for three quarters of the acreage under the cultivation of sugarcane and jute, but the rates of increase in these two regions were much slower. As in the case of the trends of acreage this indicates that the trends of yield did not necessarily depend on the relative importance of a crop in each region. The rates of increase in barley and summar rice have to be interpreted with reference to the fact that yield per acre has been assumed to be uniform in all the regions.

3.6 PROVINCIAL AND REGIONAL TRENDS IN YIELD PER ACRE IN THE QUINQUENNIAL PERIODS

During the first five years the yield per acre of nine crops which accounted for nearly nine tenths of the all-crop acreage was declining (Table 3.14). Of the individual crops the most marked drop took place in the productivity of winter rice. The yield of the three other crops of jute, linseed and tea was increasing but at slow rates. Thus the general pattern was the same as in acreage under cultivation. At the regional level the picture was mostly similar to this provincial average. The fall in the yield of jute in Burdwan Division was mainly due to four consecutive bad years in the Midnapore District. This was, however, partly neutralised by some improvement in the productivity of wheat, mustard and sesamum.

The decline in the three important food crops of winter rice, autumn rice and gram continued during the second quinquennium (Table 3.15). Conversely, the rates of increase in the productivity of jute and tea accelerated. In the case of the former this seems to reflect the greater use of the improved variety of seeds during these years of relative prosperity. The radical jump in the productivity of tobacco has to be understood with ref-

erence to the straightforward method of adjustment made in the absence of the official yield figures for the first five years. Productivity of the three other minor crops of wheat, barley and mustard increased but at slow rates.

The trends in the yield of jute, wheat and barley were the same in all the

regions. The drop in the productivity of jute for Burdwan in the preceding quinquennium was followed by a higher rate of acceleration during these years. In this respect the marked drop in the productivity of winter rice in this region may be of some significance. The pattern for the remaining crops was not always the same in all the regions. In this respect Chittagong seems to have formed a category by itself in that the yield per acre of winter rice, autumn rice, tea and linseed declined at higher rates.

During the depression years there was an increase in the productivity of all the crops except tea (Table 3.16). In course of the discussion on the nature of the official crop statistics it has been pointed out that the transfer of the crop-cutting experiments to the Agricultural Department resulted in an upward revision of the figures on standard yield for the quinquennium 1932/33 to 1936/37.¹ Now from the index of the actual yield per acre it is clear that it was only in the case of winter rice that the full effect of this bias was completely neutralised by the lower 'annawari' estimates of the seasonal condition. For the other crops the effect of the lower condition factor was partial. The magnitude of the individual crop output during the depression years noted in the earlier section must be interpreted in the light of this bias in the yield statistics. However, since the assumption in this study is that the trends in the acreage are more reliable these shortcomings do not affect the findings that

¹ These figures (Table 3.16) do not fully reflect the upward shift in the standard as the quinquennium starts from 1930/31.

Trends: individual crops

during the depression years there was a downward shift only in the production of jute. For, if it is argued that the yield per acre during these years remained more or less the same as in the preceding quinquennium the expansion of the acreage under cultivation would imply an expansion of production as well.

At the regional level the general pattern was the same as indicated by the provincial average, though in general the rates of change in Presidency Division were higher than in the other regions. The most marked exceptions were the reduction of the yield of winter rice in Burdwan and Chittagong. Almost the whole of this drop in the former region was caused by the lean year of 1935/36.

Productivity per acre of winter rice, sugarcane and linseed continued to improve during the fourth quinquennium, but only at marginal rates (Table 3.17). Conversely the yield of the remaining crops declined. This drop was much smaller than the drop in the figures on standard yield for the quinquennium beginning 1937/38. Obviously it is difficult to determine how far the reliability of the trends in individual crops was affected by this downward revision in the standard. But for reasons already pointed out this again does not affect the finding that the increased production of winter rice, autumn rice and minor commercial crops like linseed, tobacco and sugarcane was at the cost of jute.

Trends during the last five years were in sharp contrast to those in the third

TABLE 3.17 *Index of yield per acre 1935-39*

| All-crops | 107 | 100 | 98 | 121 | 109 | 94 |

quinquennium (Table 3.18) – the yield of almost all the crops declined. The highest drop was in the productivity of winter rice despite the fact that the standard was more or less the same as in the preceding quinquennium. This was mainly due to the two lean years of 1940/41 and 1942/43. The unfavourable weather conditions of 1940/41 were a common factor in the reduced yield of gram, wheat and barley. There was some improvement in the productivity of autumn rice but clearly this was too marginal to offset the decline in the other food crops. Among the five regions the rate of decline in these crops was much higher in Rajshahi and Burdwan. The consequent drop in food production in Burdwan was further aggravated by the fall in the productivity of autumn rice. The negative trend in the case of the minor cash crops was mainly due to the lower standard yield used for the quinquennium beginning 1942/43.

Thus, the percentage rates of change of the acreage and yield of the thirteen individual crops were not the same as indicated by their weighted average. While the acreage and yield of the major crops remained either stagnant or declined, those of the minor crops improved considerably. As most of these crops were grown on double cropped land in the dry season this expansion of acreage conforms to what could be expected against a background of the near-constancy of the net cropped area.

The conceivable explanations for the contrast between the trends in the yield of winter rice and the minor cash crops have been discussed in the pre-

TABLE 3.18 *Index of yield per acre 1940–44*

ceding chapter. The present chapter may be concluded by an attempt to examine what factors might have caused the wide variations at the regional level. Of particular importance in this respect is the variation between Presidency Division and the two regions of Burdwan and Chittagong. With regard to the former region it has been pointed out that the shifting of the main Ganges flow from the Bhagirathi-Hooghly River to the River Padma had caused a decrease, or a slowing down in the growth of population and a fall in soil fertility.¹ But clearly this is contradicted by the evidence presented in this chapter. This strengthens Blyn's suspicion that the effect of the change of the course of the Ganges was not an active force during the period under review.² It could, therefore, be argued that the physical conditions of Presidency and Burdwan Divisions were more or less the same. This is not, however, to deny that the conditions of some of the districts of Burdwan Division resemble those of Bihar more than those of other parts of West Bengal. But it is possible that the impact of these adverse conditions was mostly neutralised by the fact that the proportion of irrigated area was greater in this region. Considered in this context the marked contrast between these two regions seems to be perplexing. For if it is argued that the effect of the irrigation was marginal the question still remains why the gap was so marked. This is particularly relevant in view of the fact that the extension of the crop acreage in Presidency Division was mainly due to the reduction of fallow land and the increase of double cropping. It seems that in the absence of any technological innovation this would tend to lower yield per acre. Some qualitative assessment of yield per acre with reference to the conditions of the rivers, 'Khals' and 'Beels' was made in 1944–45.³ But this does not throw much light on the issue. Nor are the Settlement and Survey Reports of the districts under these two regions of much help. The usefulness of the information otherwise available is affected by the fact that these operations were made at different times.

The trends for Chittagong seem to present a less difficult problem. Of the four districts in this region the soil conditions of Chittagong proper and Chittagong Hill Tracts are much different from those of the other parts of Eastern Bengal. It is very likely that in the absence of technological improvements the productivity in these two districts was declining and led to the shrinkage of area under cultivation. This argument may

perhaps partly apply to certain parts of Noakhali district, which are inundated by the saline waters of the sea.

What could have caused the difference between Dacca and Rajshahi with regard to the trends in the yield per acre of winter rice? Again nothing definite can be said on this question, but some possibilities may be suggested. The revised series indicates some expansion of acreage under winter rice in Dacca and some retardation in Rajshahi. The extension of cultivation in Dacca was mostly due to the increase of double cropping and the reduction of fallow land. Conversely the proportion of double cropped area was much smaller in Rajshahi – only 13 per cent as against 25 per cent in the former. In the preceding chapter it has been pointed out that the extension of double cropping coupled with the pressure on fallow land could have produced an adverse effect on the yield per acre. If this possibility is accepted the difference in the rates of decline in the productivity of winter rice in these two regions would seem to lie in the difference of acreage trends itself. The effect of the increased intensity of land use could have been offset by the use of commercial fertiliser and improved varieties of seeds. But clearly there was little progress in this direction during the period under review.

PART TWO

4

PRICE ELASTICITY OF ACREAGE UNDER CULTIVATION

The question as to whether a policy of providing price incentives to cultivators should be a part of the general policy of modernising the agricultural sector in the underdeveloped countries has led to a controversy as to the applicability of the concept of supply response in a traditional agriculture. Thus, while some authors have ruled out the possibility of the play of the price-mechanism from agricultural production decisions, others have argued that peasant producers respond normally and significantly to changes in the price level.¹ To a certain degree this controversy has been confused and intensified by the failure to make explicit the three different aspects of the supply response: (1) the response of total agricultural production to changes in the terms of trade with the non-agricultural sector; (2) the response of individual crops to a change in price relative to the prices of alternative crops; and (3) the response of the marketed surplus to changes in the price. In the recent past it has been found in a number of econometric works that the acreage (in some cases output) of individual crops (category (2) above) is fairly responsive to changes in relative price.² But two other aspects of the problem have hardly been examined yet.³ In the present chapter an attempt is made to investigate whether changes in the price level had any effect on the supply of total agricultural output and the produce of individual crops (categories (1) and (2) above). As the relevant data are not available no attempt is made to estimate the price elasticity of the marketed surplus of food crops.

This chapter is divided into five sections. In the first two sections hypotheses are framed with regard to the supply response of total crops and indi-

¹ See, for example, T. W. Schultz, *Economic Crises in World Agriculture* (Michigan, 1965), p. 49. J. W. Mellor, *The Economics of Agricultural Development* (Ithaca, 1966), pp. 199–200. Authors who believe that the concept of supply response is not applicable are referred to later.

² For a summary of these findings see J. R. Behrman, *Supply Response in Underdeveloped Agriculture: A Case Study of Four Major Annual Crops in Thailand, 1937–1963* (Amsterdam, 1968), pp. 15–18.

³ The supply response of the marketed surplus has been examined by Behrman, pp. 281–315; and Raj Krishna, 'The Marketable Surplus Function for a Subsistence Crop', *Economic Weekly*, XVII (February 1965), pp. 309–20; 'A Note on the Elasticity of the Marketable Surplus of a Subsistence Crop', *Indian Journal of Agricultural Economics* XVII (1962), pp. 79–84. But there does not seem to be any work at all on the price elasticity of total agricultural production.

vidual crops. The procedural problems of estimating the supply response are taken up in section 4.3. This is followed by a discussion on the estimating formula in the fourth section and an analysis of the estimated elasticities in the last.

4.1 THE SUPPLY RESPONSE OF TOTAL OUTPUT

What is the usual response of total supply when prices are falling? During the world-wide depression of 1929–32 total world industrial production fell by 37 per cent, but agricultural production by only one per cent. In the United States the price index of non-agricultural commodities fell by 38 per cent from 1929 to 1932, while for agricultural production it fell by 54 per cent. In the same period industrial production dropped by 47 per cent, but agricultural production was actually higher in 1932 than in 1929.¹ It is a fact that such figures do not directly reflect the real magnitude of the price inelasticity of agriculture, as the impact of other non-price variables has not been considered and these years included some bumper crops. But the general pattern of the inflexibility of total production during a period of falling prices is fairly clear. When considered in the context of traditional agriculture like that of Bengal the possibility of such production behaviour becomes stronger.

The basic factor which creates this presumption that the aggregate volume of agricultural production will not decline during a period of depression is the composition of costs involved in agricultural operations. However, it is not 'cost' in the ordinary sense of the term. 'In dealing with the specific bearing of agricultural costs upon production behaviour during depression,' as Messrs Galbraith and Black point out, 'we must use the term "cost" in an inclusive sense, passing over all quibbles as to what are and are not costs, and including all disbursements of the farmer – monetary or otherwise – which may have a bearing on his activity.'² Considered in this context it is clear that in agriculture the proportion of fixed costs is much higher than in industry. Thus, the needs of food consumption of the cultivators' family – the single largest item of cost – partakes of the character of fixed expenditure. An adverse man-land ratio and a low productivity from the soil create conditions in which a large majority of the agricultural population have to live at the margin of subsistence. Now obviously during a period of depression the food requirements of the cultivators' family are not reduced. Conversely the possibility is that food requirements are increased as agriculture, in its traditional role as the 'shock-absorber', has to accommodate a part of industrial labour (though by definition very small in a predominantly agricultural country like Bengal)

¹ These figures are cited by A. Martin, *Economics and Agriculture* (London, 1968), p. 32.

² J. K. Galbraith and J. D. Black, 'The Maintenance of Agricultural Production During Depression: Explanations Reviewed', *Journal of Political Economy*, Vol. XLVI.

thrown out of employment. These considerations naturally preclude the possibility of a positive impact of falling prices on the production decision of the cultivators – in so far as it relates to the needs of domestic consumption. If there is a response at all it is likely that there will be an expansion of food production. In a traditional agriculture, production for subsistence needs is the dominant pattern. This suggests that even if there is a drop in the production of cash crops in response to a fall in the price level total agricultural output will not be price elastic.

But there are certain considerations which create the presumption that the supply of cash crops will also increase. Thus, firstly, while money income from the same volume of produce shrinks, the cultivators have to pay more for the goods they buy from the market as farm prices tend to fall faster and with bigger amplitudes than the prices of other products. Secondly, as pointed out in the preceding discussion, there is the paradox that at a time when the supply of agricultural labour is expected to be cut down in response to the changes in the market conditions it is actually increased. This results in an additional need for cash income. Thirdly, the cash expenditure involved in agriculture – rent, local taxes and interest on debt – remain fixed and thus their burden becomes heavier as a result of the drop in the price level. Such annual charges magnify the marginal utility of every unit of produce and thus outweigh the discouragement from the fall in the price level. The possibility that the output of cash crops would thus tend to increase is strengthened by the low opportunity cost of the other production inputs apart from labour – land, agricultural implements and bullock power. Thus, it would seem that, in view of the increased needs for a marketed surplus to meet fixed charges and other cash expenditures and the lack of an alternative use for the production inputs, the cultivators would devote all the available land to the production of cash crops after ensuring a supply of food for domestic consumption.

From the preceding discussion it is clear that family farms have two special characteristics which distinguish them from 'pure' firms. The latter 'purchase' almost all their inputs and sell almost all their output in the market at market prices and against money payments. As against these, on family farms a substantial or even the greater part of the output is meant for consumption by members of the family. On the input side the greater part of the inputs are supplied directly by the producers' household and their transfer-earnings are low or negligible.¹ In such a situation the aim of the producers will be to maximise the total return from the available land irrespective of a drop in the price

¹ These are discussed by Raj Krishna, 'Models of the Family Farm' in C. R. Wharton, Jr. (ed.), *Subsistence Agriculture and Economic Development* (Chicago, 1970), pp. 185–90; 'The Theory of the Farm: Rapporteur's Report', *Indian Economic Journal*, Vol. xix, No. 4 (1964), pp. 514–25.

level. Thus, the utility functions of the cultivators preclude the possibility of an adverse effect from falling prices on the level of their production.

What would be the response of farmers who employ a considerable volume of wage labour and sell the larger part of their produce in the market? At first sight it would appear that they would reduce production when there is a drop in the price level. It is true that in general the production behaviour of this class of farms conforms to that of the pure firm,¹ but a closer scrutiny suggests that their production is also likely to remain inflexible. Firstly, the surplus farmers have to retain a part of their production for domestic consumption. Secondly, they have to bear certain fixed costs. To the extent that production is meant to pay for these the behaviour of the surplus farmers would be the same as that of the small farmers. Thirdly, the other important cost item – the cost of labour – is likely to drop along with a drop in the price level. Thus, on the whole, the response of the surplus producer is not likely to be significantly different from that of the subsistence farmer.

Thus, to summarise this part of the discussion, it seems that falling prices would not lead to a drop in the level of agricultural production. Conversely, if it is believed that cultivators try to improve or at least to maintain their present standard of living then it follows that such a tendency would be strengthened during depressions and this would be reflected in those rates of growth in total production compatible with the given technological and institutional framework.

Two other forces which also have some bearing on the inelasticity of supply when prices are declining (as also at times of rising prices) are uncertainty as to future prices and weather conditions. In low income countries seasonal fluctuations in prices tend to be highly erratic and can be large. Similarly the year to year fluctuations are unpredictable and can be large. Being accustomed to such swings in prices, even in normal business conditions, the cultivators tend to ignore the sharper price movements of the earlier years of boom or depression. To this is added the significant effect of weather conditions. In Bengal agricultural produce depends so much on rainfall that it is regarded as a 'gamble in monsoon'.² Considering the magnitude of risk and the penalty

¹ That considerations of making a profit as understood in its usual sense constitute an important determinant of the production decision of the larger farmers is shown by the findings in Indian agriculture. These findings are summarised by, among others, R. Krishna, 'Land Reform and Development in Southern Asia', in W. Froelich (ed.) *Land Tenure, Industrialisation and Social Stability* (Milwaukee, 1961).

² In the USA a 10 per cent change in weather conditions has been found to imply a 4 per cent change in both the total farm output and the output of all-crops. See Z. Griliches, 'Estimates of the Aggregate United States Farm Supply Function', *The Journal of Farm Economics*, XLII (1960). For the importance of the same in the agriculture of the Punjab see R. S. M. V. Unakar, 'Correlation between Weather and Crops with special reference to Punjab Wheat', *Memoirs of the Indian Meteorological Department*, Vol. xxv, Part IV.

for error it is not surprising that the cultivators should strive to maintain a steady volume of production. However, in attempting to explain the inflexibility or upward trend in agricultural production when prices are falling too much emphasis should not be laid on these two forces alone.¹ Actually these two factors seem to play only a subsidiary, though important, role in the sense that they only add to the rigidity, which is essentially caused by the considerations described above.

Thus, it is not 'perversity' or the 'obtuseness on the part of the farmers',² but certain rational considerations which account for high aggregate production irrespective of the character of the market. Such a steady performance from the agricultural sector has rightly been regarded as a 'major national asset',³ and this is one of the considerations why in the recent past agrarian reform in the underdeveloped countries has sought to create individual peasant holdings. The underlying motive in this respect is to maximise total agricultural output before a part of the labour force is withdrawn to the other sectors.

From the preceding discussion it follows that 'perversity' will be a feature accompanying falling prices. What would be the reaction of the cultivators when the prices of their produce are increasing? This raises the wider and the much-discussed question of whether the material values of the West are foreign to the people of the under-developed countries. An extreme stand in this controversy has been taken by Boeke who maintains that the social systems of the underdeveloped countries (moulded by fatalism and conservatism) are fundamentally different from the social systems of the Western countries (dominated by common sense, reason, and practical considerations) and as such require a different economic theory.⁴

Very few scholars support this extreme thesis, but there are some who believe that certain institutional and cultural constraints such as a spirit of 'resigned contentment', 'survival-mindedness', 'natural conservatism' stand

¹ Messrs Galbraith and Black (*op. cit.*) seem to overemphasise the importance of these two forces by giving them the same weight as the other factors mentioned earlier.

Witt (eds.), *Agriculture in Economic Development* (New York, 1964), pp. 144-69.

⁴ J. H. Boeke, *Economics and Economic Policies of the Dual Societies* (New York, 1953), pp. 3-5. His thesis is based on his personal experiences in Indonesia, but he claims their general applicability to all the under-developed countries. For a critical review of his work see B. Higgins, 'The Dualistic Theory of the Underdeveloped Countries', *Economic Development and Cultural Change*, Vol. IV (January 1956), pp. 99-112. For such opinions directly relating to India, see Vera Anstey, *The Economic Development of India* (London, 1957); K. Davis, *The Population of India and Pakistan* (Princeton, 1951), pp. 213-20; Max Weber, *The Religion of*

in the way of a positive response by the cultivators to rising prices.¹ Thus according to Kusum Nair

in a situation of limited and static aspirations if a man should feel that his requirements are just two bags of paddy per year, he works for two bags, but not more. If he looks up to the stars, it is only to worship them, not to pluck them . . . in fact often the peasant does not consider it moral to want more. . . . He may and often does disdain to engage in activities yielding the highest net advantage even within the available opportunities and the restrictions imposed on him by the society to which he belongs.²

Evidently such contentions are based on the assumption that in underdeveloped societies the income elasticity of demand for leisure outweighs the cross elasticity of demand between leisure and additional income and this results in a backward bending supply curve. Obviously it is not possible here to review the different points raised by different authors in the debate on whether the supply curve of labour is really backward in the underdeveloped countries.³ What has, however, to be pointed out is that most of the discussion has been speculative in character and is based on *a priori* considerations of peasant behaviour and institutional constraints. Price responsiveness is essentially an empirical phenomenon and it is difficult to accept any thesis which is not backed by evidence. There is no denying the fact that among the peasants there are many for whom additional leisure is more important than additional income, but the realities of life of the great majority of

India (Glencoe, Illinois, 1958); *Report of the Royal Commission on Agriculture* (London, 1928), p. 6.

Neale, 'Economic accounting and family-farming in India', *Economic Development and Cultural Change*, Vol. VII (April 1952), pp. 286–305; R. O. Olson, 'The impact and implications of foreign surplus disposal on underdeveloped economies', *Journal of Farm Economics*, Vol. XLII (December 1960), pp. 1042–5. B. P. Misra and S. P. Sinha, 'Agriculture and its terms of trade with special reference to India', *The Indian Journal of Agricultural Economics* (1958), pp. 191–2; Mahesh Chand, 'Agricultural Terms of Trade and Economic Growth', *The Indian Journal of Agricultural Economics* (1958), pp. 201–2.

² K. Nair, *Blossoms in the Dust: The Human Factor in Indian Development* (New York, 1965), p. 193.

³ Thus, for example, Anne Martin confuses this issue with marketed supply, *op. cit.*, p. 29. T. W. Schultz accepts such a contention but defends it on the grounds of lack of stamina and low marginal return. See his *Transforming Traditional Agriculture* (New York, 1962), pp. 26–8.

Among many other works on the debate see also S. Rottenberg, 'Income and Leisure in an Underdeveloped Economy', *Journal of Political Economy*, Vol. LX (1952), pp. 95–101; and E. J. Berg, 'Backward-Sloping Labour Supply Functions in Dual Economies – 'The African Case', *Quarterly Journal of Economics*, Vol. LXXV, (1961).

the agricultural population preclude the possibility of such production behaviour. The large volume of rural indebtedness, which was estimated at one hundred crores of rupees¹ in 1929 and one hundred and fifty crores of rupees in 1945,² is symptomatic of the fact that the needs of a large section of the cultivators far exceeded their income – a fact which cannot be reconciled with the possibility that they had been content with their current income. Even in the case of those to whom additional leisure was more important than additional income, it is reasonable to argue that their desire for more leisure should have led them, instead of leaving a part of the land fallow, to let it out to others. In other words, in a situation where everybody was bidding for more land, even under normal market conditions, it is hard to believe that the effect of rising income would be that less land were cultivated. These considerations create a strong presumption that an increase in the price level will be followed by an expansion of the total supply.

However, the assumption that the supply response will be positive in the face of rising prices has to be interpreted with reference to two important limitations which may ‘obscure’ the degree of response expected of cultivators. In the densely populated countries the supply of land is inelastic. When cultivable land was available more and more of it was brought under cultivation not only to meet the food requirements of the growing population but also the demand for commercial crops (mostly for exports). The aggregate output expanded in response to prices, thus reflecting the peasants’ ‘capacity to respond positively to economic incentives’.³ But as a result cultivation was extended almost to the possible limits. This was particularly so in Bengal where by the beginning of our period 90 per cent of the total cultivable area was already under cultivation. The scope for the extension of cultivation in the remaining area was limited by the complex land revenue system and the known incapability for capital investment by the cultivators.

It is reasonable to assume that the cultivators of Bengal, through their long acquaintance with the cultivation of the same type of land, sowing the same crops and the use of the same techniques of production, had attained a fairly

² Government of Bengal, *Agricultural Statistics by Plot to Plot Enumeration in Bengal 1944/45*, Part I (Calcutta, 1946), p. 57.

³ H. Myint, *Economics of the Developing Countries* (London, 1973). To substantiate his argument he shows that rice exports from Burma and Thailand (produced by peasants) had increased by 10 to 13 times from 1873 to 1913 and 20 times by the late 1920s. This rapid expansion of peasant exports is all the more interesting because, unlike that of mining and plantation, it seems to owe little or nothing to outside economic resources. In the case of Bengal the rapid expansion of jute cultivation indicates the same pattern.

high degree of efficiency in the allocation of the factors of production.¹ In such a situation, when the scope for the expansion of output within the given institutional and technological framework was so limited, the response to price incentives should have been reflected more through the use of such purchased inputs as raise the yield per acre than through the extension of the acreage under cultivation. The necessity for the use of such improved inputs was realised by the Government of India and of Bengal and from 1918 the Agricultural Department devoted most of its otherwise limited resources to the popularisation of the improved varieties of seeds evolved at the experimental centres.² Due to the shortage of farms and trained staff the activities of the Department of Agriculture in the sphere of demonstration and propaganda were far from sufficient. But even then the demand for the improved seeds far exceeded the available supply. This readiness by the cultivators to make use of the new inputs for increasing their total output suggests that in general the peasant producers were not really 'survival-minded'. Thus, since the scope of increasing output either by the extension of cultivation to new areas or by the use of new inputs was limited, it is very likely that the response of total agricultural production to rising prices would remain concealed.

The second limitation to be emphasised is transport; coupled with imperfect marketing conditions. For areas more or less isolated for lack of transport and communication facilities the question of price elasticity is less significant. Considering that the means of transport were backward and the marketing system so defective in Bengal these limitations have to be regarded as of considerable importance.

4.2 THE SUPPLY RESPONSE OF INDIVIDUAL CROPS

Having examined all-crop supply responses the problems of inter-crop shifts of acreage in response to changing relative price may be discussed. The discussion will suggest that a traditional agriculture both has points of weakness and of strength which may respectively impede or facilitate shifts in land use in response to changing relative prices.

To begin with, the basic input of land with its components of soil and topography may be more suitable for the production of a particular crop than others. This would imply that even wide shifts in relative profitability may have little or no effect. Similarly, the allocative function of price will break down when several crops are sown alongside one another, provided the area is

¹ Schultz, *op. cit.*, pp. 35–52; W. D. Hopper, 'Allocation Efficiency in a Traditional Indian Agriculture' *Journal of Farm Economics*, Vol. 47 (1965), pp. 611–24.

² *Annual Report of the Department of Agriculture*, Government of Bengal for 1918 and the subsequent years.

so specific that it cannot be transferred to alternative uses. However, specificity is usually a matter of degree and, therefore, in the generality of cases this 'may effect the extent of area shifts between crops, or the promptness with which they occur, rather than preclude their occurrence altogether'.¹ Non-land inputs, however, afford a great advantage for a changing price relationship to cast its influence on the distribution of areas under different crops. In sharp contrast to advanced agriculture the capital components in traditional agriculture usually consist of livestock, labour and simple tools which are relatively unspecific to any particular crop or production pattern. Similarly, although managerial skill has some specificity it is not as fixed as in an advanced agriculture. For example, the same cultivator who can produce jute can also grow other crops such as rice with equal efficiency. This flexibility in the use of non-land inputs is a great strength of traditional agriculture in so far as the problem under investigation is concerned.

In the preceding discussion it has been assumed that cultivators based their production decisions on changes in relative market prices. So far as they market a part of each crop this would be a valid assumption. But in under-developed countries subsistence production not only comprises a high proportion of what is produced, but output of a particular crop is often retained for domestic consumption. This simultaneous production for domestic consumption and cash needs introduces a discontinuity in the play of the impact of changing relative price as the cultivators naturally attach a higher price to production which is meant for family consumption. Thus, for a cultivator who markets only a small proportion of the rice he grows a relative fall in its price may make it profitable to reduce the cultivation of this crop and increase the area under jute – the alternative crop. The cultivator may respond to this by transferring only that portion of the acreage under rice which is sold in the market. He cannot be expected to transfer from the production of rice any area beyond this point, as in that case he will have to pay the retail price for the purchase of rice while getting the wholesale price for the sale of jute.

The effect of the above considerations on the allocative function of price is magnified by the two other factors referred to earlier – uncertainties of future prices and weather conditions. These two factors being so unpredictable the cultivator will naturally attach still greater importance to production for domestic consumption. In other words, he will hesitate to put under the cultivation of subsistence crops an area less than he considers sufficient to meet his requirements, as the penalty for under-attainment of a given level of food

¹ Dharm Narain, *Impact of Price Movements on Areas under Selected Crops in India, 1900–39* (Cambridge, 1965), p. 5.

crops is much greater than the benefits of over-attainment. Thus, it seems that relative prices would be a relevant factor only in the case of that proportion of individual food crops which is marketed. But since the proportion of marketed surplus is by definition small in an underdeveloped country the price elasticity of such crops is likely to be insignificant.¹

How far could the specific conditions in Bengal be expected to conform to this general pattern? It is difficult to obtain reliable estimates of the proportion of food crops sold in the market. However, the available estimates and the wide disparity in the distribution of both operational and ownership holdings of agricultural land in Bengal² clearly show that at least a section of the cultivators could produce a marketable surplus. This would create the presumption that, given the scope for substitution with alternative crops, the price elasticity of food crops would also be positive, though very low. The importance of the availability of alternative crops is obvious as the cultivators cannot be expected to respond to a shift in the price level if there is no scope for substitution. The sowing season of a particular crop may be such that the cultivators cannot sow their land with an alternative crop which is more profitable. Obviously in such circumstances the question of changing prices is not of much significance. It seems that winter rice – the largest single crop – belongs to this category. On the other hand, autumn rice is directly alternative to jute. These considerations suggest that the expectation that the supply response will be normal but low will be fulfilled only in the case of autumn rice.

Thus, to sum up this part of the discussion, it seems that (a) total supply would not be responsive to changes in relative price, but (b) there would be considerable impact from changing relative price on the production of individual crops, and (c) such impact would be more marked in the case of crops which are wholly or mainly sold in the market.

4.3 PROCEDURAL PROBLEMS OF ESTIMATING SUPPLY RESPONSE

In the preceding discussion reference has mostly been made to the price elasticity of total output and the output of individual crops. But there are certain difficulties in correlating price with subsequent supply in estimating

¹ This part of the discussion is based on the work by Mellor, *op. cit.*, pp. 36–41.

The wider question of the price elasticity of the marketed surplus of a subsistence crop which also involves the problem of the price elasticity of the demand for food is not examined in this study. The purpose here is only to emphasise the restricted relevance of the price mechanism in the production of food crops.

² According to the information available from the *Agricultural Statistics* (*op. cit.*), 24 per cent of the rural households held more than 50 per cent of the total area, p. 51; According to the *Report on the Marketing of Rice in India and Burma* (Delhi, 1941), 44 per cent of total rice output, the largest single food crop in Bengal, was marketed, p. 35.

the response of cultivators to changes in market conditions. Reference has been made to the importance of weather conditions in Bengal agriculture. Since the cultivators have no control over natural forces they have no control over a yield per acre either. Therefore, the mere fact that a change in output follows a change in price cannot indicate the level of the cultivators' intended production. To obviate such a complication it is usual to correlate price with acreage, over which the cultivators have greater control. A similar procedure has been followed in the present work.

The question that now arises is: what is the price to which the acreage under total cultivation and the cultivation of individual crops can be expected to respond? The actual production process in agriculture introduces a lag between the decision with regard to the utilisation of land, and realised production. So at the time of decision making the cultivators have to form expectations about the price which they think is likely to prevail in the next season. Expectations of future prices are shaped by a multitude of influences, but no specific information about them is available. Nor can many of them be quantified. Therefore, it is usual, merely as a convenient way of summarising the effects of these diverse influences, to represent actual price as a function of past price.¹ Some authors have used the harvest prices, while others have used the prices prevailing during the pre-sowing season. But it is clear that each of these particular past prices represents only a very short-run market phenomenon reflecting the equilibrium of the manifold forces present in the market at that time. These considerations render inadequate an attempt at approximating expected price to a particular price in the past. This inadequacy may be removed by assuming a Nerlovian approach of estimating 'expected normal price' on the basis of prices over a number of years in the past, supposing that the influence of more recent prices will be greater on them than the influence of less recent prices.²

Expressed in mathematical terms

$$P_t^* = A_1 P_{t-1} + A_2 P_{t-2} + \dots + A_n P_{t-n} \quad (1)$$

where P_t^* is the expected price for year t and P_{t-1}, \dots, P_{t-n} are the observed prices of the previous periods and

$$\begin{aligned} A_1 &> A_2 \dots > A_n \\ A_1 + A_2 + \dots + A_n &= 1. \end{aligned}$$

¹ Marc Nerlove, *The Dynamics of Supply: Estimation of Farmers' Response to Price* (Baltimore, 1958).

² Nerlove, *op. cit.*, pp. 50–5. The formulation that follows is quite similar but not identical with that of Nerlove.

Such a dynamic model represents a distinct improvement on all past approaches. But, for reasons discussed later on, in the present study it is proposed to use a particular past price as a proxy for the expected price.

The next question that has to be dealt with is: should this particular price be the harvest price of the previous year or the pre-sowing price? The expectation formations are not influenced by the same set of prices for all classes of cultivators. The retention power for the bulk of small-scale producers is very limited and they market their produce soon after the harvest and they know that whatever prices were in the pre-sowing period they would fluctuate around the level of the current harvest prices during the next season. On the other hand, because of their greater retention power the big cultivators market a considerable portion of their produce at a time when prices are higher. In this connection it has to be added that the bulk of the cultivated area is usually held by this class of cultivators and their production decisions are more market-oriented.¹ However, there are two considerations which would seem to suggest that the harvest prices would be a better approximation of the expected price. Firstly, it seems that on the whole the larger part of the produce sold during the year is marketed during and immediately after the crops are harvested. Secondly, in the case of certain crops, such as sugarcane, this is the time when plans are made for the next season. Pre-sowing prices may come at a time so close to the actual sowing that the cultivators find it difficult to shift areas between crops in the same season. In view of these considerations harvested prices of the previous year have been taken as an indicator of the expected price on which to base the production decisions for the current year. In the construction of the composite price index against which all-crop acreage is expected to respond the harvest price of every crop has been weighted by the proportion of the total area under its cultivation.

The theoretical supply curve is drawn on the assumption that other prices remain the same. But as other prices do not really remain unchanged it would be pointless to correlate only the crude market prices with the subsequent acreage under cultivation of all the crops. This necessitates correction to give the real purchasing power of the cultivators' produce. Therefore, the composite index of the prices of all the crops has been deflated by an index of the prices of the daily necessities of life as constructed by the Government of India.²

¹ That the proportion of area under commercial crops increases with the increase in the size of holding has been found in India. Source: *The National Sample Survey*, 8th round, No. 30, *Report on Land Holdings* (2) (Delhi, 1960), cited by Narain, *op. cit.*, p. 161.

² Director General of Commercial Intelligence and Statistics, *Index Number of Indian Prices* (annual). The harvest prices of the crops are taken from the *Agricultural Statistics of India*, Vol. 1 (annual).

The problem of selecting the value of a crop whose variations will be positively correlated with those of its area is more complicated. Some attempts have been made to correlate the acreage under one crop with the price of that crop only. Clearly such a procedure suffers from serious limitations. If it is expected that the variations of area under crops will be a function of changing profitability, the prices of other crops must also be taken into consideration. But this raises another problem: what will be the composition of the 'other crops' the prices of which will be used to 'correct' the prices of the crop in question? Should they include all the single crops produced in a country or the prices of alternative crops only? Evidently the former method is likely to introduce some bias into the estimated price elasticity of a particular crop. But in spite of this shortcoming this procedure has been widely used in the United States. This could be due to the fact that most of the major crops are grown over a wide area and the number of relevant alternatives to a particular crop is very large. But in Bengal the scope of such substitution is somewhat limited. Thus, the crop which directly determines the opportunity cost of growing jute is autumn rice as these are the only two crops sown during the months from March to May. The other variety of rice – winter rice – is an alternative crop in a somewhat restricted sense in that the transplanting season of this crop (July to September) overlaps with the harvesting period of jute. After an early jute harvest 'Aman' paddy may be transplanted on the same land if the weather conditions are favourable, but this involves a loss of yield for both the crops. The other crops like mustard, linseed, sesamum, wheat, barley and gram are usually sown during the months from November to January. Thus, clearly these crops cannot be treated as alternatives to jute or autumn rice. The cultivators cannot be expected to plan the production of either jute or autumn rice on the basis of the relative price of one of these crops. It is true that the pattern of rotation among different crops sometimes makes the task of selecting the various alternative crops rather difficult. But this does not seem to justify the procedure of treating all 'other crops' as alternative to every individual crop. Therefore, in the present study price relatives of the different crops have been constructed on the basis of the prices of those specific crops which seem to directly determine opportunity cost. In certain cases when a straightforward selection is difficult different combinations have been tried. These are elaborated in the course of the discussion on the estimated elasticities.

Apart from price the two other explanatory variables included in the model are yield and the mean of the quantum of rainfall during the sowing season. The inclusion of the former is justified by the fact that it is not only the price per unit of produce but also the volume of produce per unit of land which may influence the decision of the cultivators. Rainfall is included on the assumption

tion that this may interfere with the actual sowing of the planned acreage with crops.

4.4 ESTIMATING MODEL

Prior to Nerlove's work it was usual to approximate the desired planted area to the actual sown area, and the expected relative price to the prevailing price in the previous period, in the studies of United States' agriculture and in studies of underdeveloped countries even subsequent to Nerlove's work. Nerlove tackles the obvious limitations of such 'crude' approximations in his adjustment and expectational model. The area adjustment model states that the area actually sown with a crop in production period t equals the area actually sown in the previous period plus a term proportional to the difference between the desired planted area in the t th period and the actually sown area in the previous period. According to his expectational model the expected relative price in production period t equals the expected relative price in the previous period plus a term proportional to the difference between the expected relative price and the actual relative price in the previous period. Thus, while the latter is supposed to reflect the manner in which past experience determines the expected value of the variable such as price or yield which in turn determines intended production, the former reflects the technological/institutional restraints which allow the cultivators to realise only a fraction of the intended production. In the light of the uncertainties of price and yield and many other restraints already referred to it is clear that both these types are of great importance in an underdeveloped agriculture. Therefore, ideally a model should be developed specifying a separate lag coefficient and different adjustment lag coefficient for each expectational variable, but such a model involves serious estimation problems.¹ Therefore the model used in this study provides for only an adjustment lag. This is as follows:²

$$A_t^* = a + bP_{t-1} + cY_{t-1} + dR_t + U_t \quad (2)$$

$$A_t - A_{t-1} = B(A_t^* - A_{t-1}) \quad (3)$$

¹ Nerlove, *op. cit.*, pp. 236–40.

² A different method of estimating price elasticity has been suggested by Z. Griliches, 'Distributed Lag: A Survey', *Econometrica*, Vol. 35, No. 1. An attempt to follow this method raises two main difficulties. Firstly, the volume of computation will be more complicated and much larger. Secondly, since this method is not followed by other authors, it will not be possible to compare the estimated elasticities. For a criticism of Nerlove's model see also F. M. Fisher, *A Priori Considerations and Time Series Analysis* (Amsterdam, 1962), pp. 21–58; H. W. Watts, 'Review of Nerlove, Distributed Lags and Demand Analysis for Agricultural and other Commodities', *Journal of Farm Economics*, Vol. XL; G. E. Brandow, 'A Note on the Nerlovian Estimate of Supply Elasticity', *Journal of Farm Economics*, Vol. XL (1958).

A_t^* is the acreage the cultivators would sow with crops in the year t if there was no difficulty of adjustment. A_t is the actually sown area.

P is the relative price of the crop in question, i.e. the harvest price of the crop deflated by the prices of the alternative crops.

Y is the relative yield of the crop.

R is the quantum of rainfall during the sowing season.

U is the error term.

B is the Nerlovian coefficient of adjustment.

It is assumed that the cultivators are able to vary the acreage under a crop in any year only to the extent of a fraction B of the difference between the acreage they would like to sow and the acreage actually sown in the previous period.

Equations (2) and (3) yield the following estimating equation:

$$A_t = a_0 + b_2 P_{t-1} + b_3 Y_{t-1} + b_4 R_t + b_5 A_{t-1} + V_t \quad (4)$$

where $a_0 = aB$, $b_2 = bB$, $b_3 = cB$, $b_4 = dB$, $b_5 = (1 - B)$ and $V_t = BU_t$.

It is, however, possible to build an expectational model on the assumption that the expectation lag coefficients of the different variables are identical. Thus,

$$A_t = a + bP_t^* + cY_t^* + dR_t^* + U_t \quad (5)$$

$$P_t^* - P_{t-1}^* = B(P_{t-1} - P_{t-1}^*) \quad (6)$$

$$Y_t^* - Y_{t-1}^* = B(Y_{t-1} - Y_{t-1}^*) \quad (7)$$

$$R_t^* - R_{t-1}^* = B(R_{t-1} - R_{t-1}^*) \quad (8)$$

This model yields the following estimating equation:

$$A_t = a_0 + b_2 P_{t-1} + b_3 Y_{t-1} + b_4 R_{t-1} + b_5 A_{t-1} + W_t \quad (9)$$

where $a_0 = aB$, $b_2 = bB$, $b_3 = cB$, $b_4 = dB$, $b_5 = (1 - B)$ and $W_t = U_t - (1 - B)U_{t-1}$.

The two estimating equations (4) and (9) are the same except for the lag in R and the error term which is serially correlated in (9) but not in (4). If it is assumed that U_t in this second model is serially uncorrelated, then W_t in the estimating equation (9) is automatically serially correlated, since $W_t = U_t - (1 - B)U_{t-1}$. On the other hand, if W_t is supposed to be serially independent, U_t is serially correlated.¹ Secondly, the assumption of identical expectation may be questioned. Thirdly, if different coefficients of expectation are specified for each of the additional lagged explanatory variables, the number of variables in the estimating equation becomes very large. Even

¹ US Department of Agriculture, *Distributed Lags and Demand Analysis for Agricultural and Other Commodities* (Agricultural Handbook No. 141, 1958), p. 76.

for a model with two variables the estimating equation will have six explanatory variables.¹ With only twenty to thirty observations available in most of the cases, many degrees of freedom are lost in estimation. Lastly, the more serious objection is that the estimates of the regression coefficients thus obtained are not unique.² In view of these considerations the 'adjustment' model is used in this study though it has to be admitted that this oversimplifies the expectational side of the problem.

The same model has been used for estimating the price elasticity of the all-crop acreage. In such a case P_{t-1} , Y_{t-1} and R respectively refer to the composite index of the price of all the crops, weighted yield of all the crops in the previous period and the quantum of rainfall throughout the agricultural season (March–February).

In order to obtain a direct estimate of the elasticity of acreage with regard to the different explanatory variables both the dependent and the independent variables have been transformed into their logarithms.

4.5 ESTIMATED ELASTICITIES

The *a priori* considerations for the inclusion of different explanatory variables have been discussed. The actual computations have been done with different combinations of variables in order to obtain an equation which explains the highest degree of variance in the acreage under the cultivation of individual crops and all the crops taken together. The estimated short-run and the implied long-run elasticities are presented in Table 4.1. Standard errors of these elasticities are shown in parentheses. All these estimates have, however, to be interpreted with reference to the quality of the crop statistics discussed in the first chapter.³ Findings of other authors on the same or similar crops are also presented in order to facilitate comparison.

4.5a *Jute*. In equations (1) and (2) autumn rice, and in equations (3) and

¹ *ibid.*, p. 60.

² *ibid.*, p. 62.

³ In the official explanations for the variations of 10 per cent or above in the acreage under cultivation as given in the *Agricultural Statistics of Bengal*, it was often pointed out that these were due to shifts in the price level. It is difficult to say definitely if these annual variations in the officially published data were influenced by the subjective judgement of the reporting agencies. This also applies to the price statistics used in this study. These prices represent the median of the district figures (reported in the *Season and Crop Report*) which often remained the same for several years. Price statistics for the province as a whole are available from the *Agricultural Statistics of India* (Annual), Vol. 1. The quality of these data is discussed by R. C. Desai, 'Consumer Expenditure in India, 1931–2 to 1940–1', *Journal of the Royal Statistical Society*, Vol. cxi (1948), pp. 261–98.

(4) both autumn and winter rice have been treated as alternative crops. In both the cases there is no significant elasticity either with regard to expected yield or the quantum of rainfall during the sowing season. Conversely all four equations indicate that two thirds of the variance in area sown with jute is positively associated with changes in the expected relative price and these estimates are significant at less than the 0.1 per cent level. The implied long-run elasticity is higher than that estimated by Rabbani and Stern, but the short-run elasticity is smaller than found by the latter. This may be due to the fact that while Stern deflates the wholesale prices of jute by the prices of all other crops including rice, Rabbani includes, apart from Bengal, other jute-producing areas of India (Assam, Bihar and Cooch Bihar). The acreage under cultivation revised on the basis of the discrepancies found between the official estimates of jute production and the 'actuals' as determined from the trade statistics indicates a slightly lower elasticity with regard to expected price. But even then both the long-run and short-run elasticities are much higher than for a similar crop (cotton) in the USA. This may be due to the lesser scope for substitution for the latter and perhaps due to the relative specificity of managerial skill and resources in an advanced agriculture.

4.5b *Sugarcane*. This crop occupies the land for most of the year, and, therefore, the three other major crops of winter rice, autumn rice and jute have been treated as alternative crops. In both equations (1) and (2) (see Table 4.1) the pattern is completely different from that for either jute or sugarcane in the other Indian Provinces¹ – there is no significant elasticity of acreage with regard to expected relative price. Conversely, the model indicates a fair degree of response to the improvement in yield. The implied long-run elasticity is, however, considerably higher than unity. The low elasticity of adjustment seems to be due to the fact that this crop is the most expensive in terms of the required intensity of cultivation, weeding, fencing and growing time. However, it is clear that since, despite this high cost, the cultivators were favourably responding to the use of the improved varieties of seeds, the total sale proceeds of planting sugarcane must have made the production of this crop more profitable in relation to alternative crops. Thus, it seems that it was not higher relative price as such, but the success of the Agricultural Department in making the relative product-price per unit of land (by the popularisation of the improved varieties of seedlings) more attractive, which led to the remarkable expansion of sugarcane cultivation in Bengal.

¹ A significant price-acreage relation has been found in the case of the Punjab, United Province and Madras. For details, see Narain, *op. cit.*, pp. 84–106.

4.5c Winter rice. In equations (1) and (2), jute and in equations (3) and (4), all the 'rabi' crops have been treated as competitive crops. The first formulation is suggested by the type of competition between these two crops shown in the elasticity of acreage under jute. 'Rabi' crops have been treated as substitutes in view of the fact that the harvesting of winter rice releases land at a time which is usually too late to enable the cultivators to raise a 'rabi' crop on the same land. There is no significant response of the acreage under this variety of rice in any of the four equations. This finding seems to conform to what could be expected in Bengal agriculture. As mentioned earlier, perhaps the larger portion of this crop was meant for domestic consumption by the members of the cultivators' family. Secondly, the planting season of winter rice is such that there is little scope for substitution with an alternative crop.¹

As to the impact of the two other variables, winter rice is the only crop which shows a significant, though small, elasticity with regard to the quantum of rainfall during the sowing season (July to September). Again, this finding conforms to what could be expected for this crop. As winter rice is transplanted, the ploughing of the land is not enough; there must be a sufficient quantum of rainfall to facilitate the transplantation of the seedlings and their subsequent growth.

4.5d Autumn rice. The price and yield of autumn rice have been deflated by the corresponding figures for jute. The expectation that the cultivation of this crop, though mainly for domestic consumption, would be price elastic is borne out by the findings in both equations. The short run elasticity which is significant at the 5 per cent level, is similar to those found in Bangladesh. As in the case of winter rice and jute, there is once again no significant elasticity with regard to changes in relative yield. But so far as the impact of rainfall is concerned there is a significant difference between these two varieties of rice. However, this absence of any impact of rainfall on the acreage under autumn rice (as also under jute) conforms to what could be expected. While winter rice is transplanted, autumn rice and jute are sown. This creates the expectation that if in a particular season the quantum of rainfall is not too small or too heavy this would not stand in the way of sowing the desired area with autumn rice and jute.

4.5e Mustard In terms of acreage under cultivation mustard is the second largest commercial crop. As this crop is grown during the dry months from November to January its prices and yields have been deflated by the prices and

¹ In Thailand the magnitude of the price elasticities of rice cultivation has been found to be dependent upon the availability of economically attractive alternatives to rice cultivation. Behrman, *op. cit.*, pp. 303-5.

yields of all the 'rabi' crops. As in the case of jute and autumn rice there is once again no significant response to relative yield or rainfall. The elasticity of acreage with respect to expected relative price is more or less the same in both the equations, but these are significant at the 10 per cent level. Such a weak response may be attributed to two important factors. Firstly, three of the four alternative crops (gram, barley and wheat) are food crops and, therefore, it seems that their cultivation would remain more or less inflexible. This limits the desired level of increase in the acreage under mustard though there may be an improvement in the relative price. Secondly, mustard is grown as a second crop in the same agricultural year. Therefore, the level of production is likely to depend more on the scope offered by the desired rotation between the major crops than by the changes in relative price.

4.5f *All-crop acreage.* The actual findings seem to substantiate our hypothesis that in a traditional agriculture characterised by an adverse man/land ratio no significant response of all-crop acreage to changes in relative price can be expected. This relative inelasticity of total acreage under cultivation cannot, however, be interpreted as indicating that the total supply in Bengal agriculture was not positively related to an increase in the price level. As argued earlier, since the scope for further extension of cultivation was limited, the impact of rising prices could have been reflected in (a) the greater use of new inputs and (b) changes in the crop-mix as a result of the shift of acreage under individual crops in response to changes in relative price. In this latter respect it has been seen that acreage under three individual crops is price elastic and there is no systematically opposite trend in the case of the most important crop (winter rice). Therefore, it may be assumed that the total supply in Bengal agriculture was price responsive.¹

To sum up, out of the five crops included in this study acreage under jute and autumn rice was responsive to changes in relative price and that of sugarcane to improvement in relative yield. In the case of winter rice, only rainfall had some impact on the acreage under cultivation. Therefore, it may be suggested that though the total acreage under cultivation was not price elastic the Bengal cultivators were trying to maximise their proceeds from the available resources by the shift of areas to such crops as were

¹ For further elaboration of this point see Raj Krishna, 'Agricultural Price Policy' in H. M. Southworth and B. F. Johnston (eds.), *Agricultural Development and Economic Growth* (New York, 1967). This author cites the significant evidence that in many countries – e.g. Spain, Egypt, Yugoslavia and Mexico – changes in the cropping pattern alone contributed 15 to 20 percent of the increase in total crop output during the period 1948–50 to 1960–62.

Price-elasticity of acreage under cultivation

relatively more profitable, either due to an improvement in relative price or relative yield per acre. As indicated in the case of the price elasticity of autumn rice, such variations of area were not confined to cash crops only. In other words, they seem to have taken such rational production decisions as were desirable within the given technological and institutional constraints.

5

CAPITAL IN AGRICULTURE

Economic development is generally defined as the sustained growth of per capita output. Among the factors which account for the growth of output a crucial role is usually assigned to capital and capital formation.¹ Theoretically, this dominance of capital theory in the literature on growth economics is partly due to the popularity which the Harrod-Domar model has gained, especially through its application to the economic development of the underdeveloped countries. In this model the rate of economic development is a function of two factors: (a) capital formation and (b) the capital/output ratio; and accordingly development policies have been described as aiming to increase the former, reduce the latter or to achieve both. Much effort has gone into the estimation of the capital/output ratio and the measurement of the contribution of the physical capital stock to past economic growth and the requirements for future progress. Some investigations have shown considerable differences over time in the relation between physical capital and output, but none of them has suggested any ground for doubting the importance of capital formation in economic progress.

Along with this emphasis on the role of capital, another concept which has been widely discussed is that the underdeveloped countries are plagued by a 'vicious circle'.² The circle theory emphasises that since per capita income in these countries is low, little remains as a surplus after consumption needs are fulfilled. The low level of real income is, in turn, due to the lack of an adequate capital stock. From the findings presented in the preceding two chapters it is clear that in spite of the relative abundance of labour there was hardly any increase in yield per acre and, against a background of rapid population growth, this meant a decline in per capita output. Such a finding

¹ See, for examples, W. A. Lewis, *The Theory of Economic Growth* (London, 1955), particularly the chapter on capital. W. W. Rostow, *The Stages of Economic Growth* (Cambridge, 1971), pp. 39–44.

² This thesis is presented by different authors in several distinctly different variants. These are analysed by P. T. Bauer, 'The vicious circle of poverty' in I. Livingstone (ed.), *Economic Policy for Development* (London, 1971), pp. 19–36. See also Tamas Szentes, *The Political Economy of Underdevelopment* (Budapest, 1971), particularly pp. 50–60. For the present purpose only the supply aspect of capital formation is discussed.

creates a strong presumption that the agrarian economy of Bengal was characterised by the same 'vicious circle' of low income and the consequent low capital formation.

In the present chapter an attempt is made to investigate this aspect of the agricultural economy of Bengal, i.e. the trend of capital formation. The three specific questions raised are: (a) what was the trend of the stock of capital, (b) how does this trend compare with those in production, land and the labour force engaged in agriculture, and (c) did the weights of the different categories of physical capital change over time? These questions are analysed, in the light of the available materials, both at the all-Bengal and regional levels.

5.1 PROBLEMS OF DEFINITION

Such a study involves a good deal of difficulties. These arise partly from the controversies associated with capital theory and partly from the nature of the available data. With regard to the former the debate among economists is concerned with the two related problems of the definition and measurement of capital. It would be tedious to review this controversy in detail. However, some indication must be given of its nature in order to illuminate the subsequent discussion of our findings. The problem of definition is taken up first.

According to a United Nations publication capital goods are 'all goods produced for use in future production processes — machinery, equipment, plant, buildings, other construction and works, and producers' stock of raw materials, semi-finished and finished goods'.¹ Evidently according to this view only those goods are capital goods which are produced for use in future productive processes. On the other hand, some authors argue that the definition of capital should not be so narrow as to include only the physical assets. Thus, it is believed that if long-term increase in per capita income is described as economic growth the definition of capital should be broadened to include all uses of current output that contribute to such an increase. Thus capital formation should include, apart from additions to the physical stock, expenditure on health, education, recreation and material luxuries that contribute to the greater productive skill of the labour force.² Recently

¹ *Concept and Definition of Capital Formation*, UNO 1955, p. 7, cited by P. V. John, *Some Aspects of the Structure of Indian Agricultural Economy, 1947/48 to 1961/62* (Delhi, 1968), pp. 139–40.

² See for example Simon Kuznets, 'International Differences in Capital Formation and Financing' in National Bureau of Economic Research, *Capital Formation and Economic Growth* (Princeton, 1955), p. 21.

it has become usual to describe such non-physical development expenditure as 'human capital'.

One cannot deny the fact that ideally a study of capital formation should include such expenditure as makes the members of a community more productive. But over and above the problem arising from the non-availability of relevant data such an attempt to broaden the definition of capital creates many difficulties. Thus, conceptually it is difficult, if not impossible, to separate human capital on the one hand and physical output on the other. Secondly, there are problems of measurement, i.e. imputation and allocation of costs and valuation of returns. These difficulties have weighed heavily in the decision to exclude human capital even in major studies on capital formation.¹ Therefore, the present study is confined to an analysis of only the physical capital assets involved in Bengal agriculture.

The question that now has to be discussed is whether land should be regarded as an item of capital. Like buildings land is a durable physical asset, but in economic theory only the former is regarded as capital. This distinction is made on the grounds of what has been regarded as the fundamental differences in the origin and supply of land and other durable producers' goods. Thus, it has been argued that land is a free gift of nature and fixed in supply, whereas capital is a 'produced means of production' and its supply responds to the human decision of investment. As against this argument it has been pointed out that 'Granted that the gross acreage of a country or region cannot be altered, it is still possible to change greatly the productive acreage and the productivity of acreage already in use by means which closely resemble methods by which buildings and equipment are increased'² and, therefore, land should be included as an item of capital. It is difficult to differ from this line of argument, but it seems that land can be so treated only on recognition of the fact that this procedure does not take into consideration the expenditure of money and effort required from the cultivators. The increase of 'productive acreage' or the extension of cultivation to new areas may be achieved by the investment of money and effort in such things as clearing, drainage and irrigation. On the other hand, the productivity of land already under cultivation may be increased by, apart from the more intensive use of labour and implements, investment on fertilisers, prevention of soil erosion and soil depletion. Both process would involve investment in land, but no information is available on the volume of all such investments. Therefore, it is clear that new land which is brought under cultivation during

¹ See for example A. S. Tostlebe, *Capital in Agriculture: Its Formation and Financing* (Princeton, 1957); Kuznets, *op. cit.*; Henry Rosovsky, *Capital Formation in Japan* (New York, 1961).

² Tostlebe, *op. cit.*, pp. 4–5.

See also L. M. Lachmann, *Capital and its Structure* (London, 1956), p. 11.

a particular period of time should be treated as an item of capital. This will be an index of the investment of money and effort made by the cultivators for the creation of additional 'productive acreage'. From this it is also clear that this procedure does not take account of all the direct investments made in land already under cultivation. This follows from the fact that, along with other assets, land is valued at a constant price and, thus, all changes in the volume of direct investment are ignored. It is likely that in an economy where the scope for the extension of cultivation is limited but the supply of labour is abundant some improvement takes place at least in such investments as depend mainly on increased physical labour. Thus, it seems that in including land as an item of the cultivator's stock of capital it has to be specifically understood that this represents not the whole but only a part of the investment of money and effort made by members of a community within a particular period.

5.2 PROBLEMS OF MEASUREMENT

The controversy with regard to measurement concerns the selection of a unit in which to aggregate the heterogeneous mass of capital items into a homogeneous collection. Usually the following four methods are advocated to evaluate the different items of capital: (a) in terms of their value expressed in some unit of purchasing power, (b) their contribution to the future flow of product, (c) the cost of labour involved in the construction of capital goods and (d) the prices of the existing goods required to make them. It is not necessary to review the controversy relating to the merits of each of these procedures. The method followed in this study is to weight the different items of capital according to their market prices at a particular point of time, e.g. at t_1 , and to keep the weight constant at periods t_2, t_3, \dots, t_n .

There is, however, one point which merits particular attention. This procedure of taking the market value of the stock assumes the equality of marginal cost with marginal revenue, which under perfect competition equals the price. Does this assumption hold good over a period of time? In other words, it has to be asked if, in the estimation of the cultivators, the weights of the different items remain constant. Clearly nothing definitive can be said on this question. It would, therefore, be interesting to see if alternative estimates made on the basis of prices prevailing at different points of time show any significant differences. But no such attempt can be made in view of the non-availability of the relevant information.

Another problem is created by depreciation. When the stock of physical capital involved in an economy is compared at two points of time without making any allowance for depreciation, it is assumed that either the stock is

equally new or equally depreciated. In other words, that the rates of depreciation and replacement balance each other. In the absence of any relevant data it is difficult to say whether this is a valid assumption regarding Bengal agriculture during the period under study. Therefore, the estimates presented in this chapter have to be taken as estimates of gross capital formation.

It is desirable that estimates are presented not only of the trends of capital formation, but also of its magnitude. In other words, since capital formation implies saving it is important to gain some idea about the proportion of income represented by such savings. But there are two difficulties which do not permit any such attempt. Firstly, as pointed out later, there is the non-availability of data on the working capital of the cultivators and no reliable price statistics of even the limited number of physical assets selected for this study. Secondly, even if these data were available there is the further problem created by intersectoral flows. If agriculture was a closed economy it could have been taken that all the investment outlays in this sector were financed by the rural households themselves. In other words, the annual flow of investments would have been matched by the flow of savings. But this equality is complicated by the flow of capital between the agricultural and the non-agricultural sectors – on which no data are available. In view of these difficulties no attempt can be made to relate capital formation to per capita income in the agricultural sector. Instead only the broad indications discernible are pointed out.

5.3 SOURCES OF DATA, THEIR COVERAGE AND ADJUSTMENTS

Capital assets selected for this study include: (a) land, (b) buildings, (c) animal labour and (d) farm implements. In view of the non-availability of relevant information no attempt has been made to estimate the trends in working capital involved in Bengal agriculture. Thus, clearly the concept of capital as used in this study becomes more restrictive than implied by the phrase ‘physical capital’.

The sources and nature of crop statistics in Bengal have been discussed earlier. For the present purpose it has to be asked (a) what categories of land should be included and (b) should land to be included refer to a particular point in time? As to the first question the usual procedure has been to include only the net cropped area and the area currently left fallow by the cultivators.¹ But there is one consideration which suggests that this procedure of including net cropped area as against total cropped area (net cropped area + double cropped area) is defective. In an underdeveloped agriculture where the scope

¹ T. Shukla, *Capital Formation in Indian Agriculture* (Bombay, 1965), p. 64.

for the extension of cultivation to new areas is limited the increase in double cropped area represents the expenditure of money and effort by cultivators to increase total output. Therefore, in the present study land as an item of capital includes total cropped area and the area currently left fallow.

The second question is important because there were considerable year-to-year fluctuations in the acreage under cultivation. Therefore, the inclusion of the acreage of only the quinquennial Livestock Census years may introduce some bias in the estimates. In order to obviate this difficulty figures have been calculated on the basis of a three years' average centred on the census years. A similar procedure has been followed in the case of all-crop output.

5.4 DRAUGHT ANIMALS

Data on livestock labour are available from the *Quinquennial Cattle Census Reports*. In the first three reports published by the Government of Bengal separate estimates of 'plough cattle' were presented. It is common knowledge that the same livestock labour may be used for, apart from ploughing land, such purposes as carrying crops from the fields to the cultivators' houses or from the latter to the rural markets. Of greater importance is the fact that the same work animals may be used for non-agricultural purposes. Such uses are frequent, particularly during the relatively slack season of the year. In view of this flexibility in the use of livestock labour in the rural areas it is difficult to accept the official estimates as estimates of only 'plough cattle'. However, this would not have created a major problem if the method of classification was uniform during the entire period. But it seems that a change was introduced for 1940 and 1945. Firstly, whereas separate estimates of 'plough cattle' were provided in the first three census reports, no such category was maintained in the last two. Instead the number of bovine population 'kept for work only' was separately shown. In view of the pattern of use of livestock labour referred to earlier it is clear that this latter method of classification was an improvement on the earlier ones. Secondly, while according to the first three censuses 'plough cattle' included only bulls, bullocks and male buffaloes, in 1940 and 1945 the number of cows and female buffaloes (over and above the above three categories) 'kept for work only' was also presented. It is difficult to say how far conceptually these two categories are strictly comparable¹ but even if they are assumed to be so it is clear that the scope of the latter category was wider. In view of these difficulties, the available data

¹ Figures on bulls, bullocks and male buffaloes presented in Appendix VII in *Livestock Census Reports* and designated as 'plough cattle' are slightly smaller than the corresponding figures shown in Appendix IV. It is not known on what criterion the figures in the former appendix were determined.

on bulls, bullocks, cows and buffaloes (male and female) have been taken for present purposes to represent the total livestock labour available for crop production.

5.5 AGRICULTURAL IMPLEMENTS

Quinquennial cattle censuses up to 1930 provided information only for ploughs. From 1940 ploughs were divided into wooden and iron ploughs and items such as sugarcane crushers, oil engines, electric pumps and tractors were also included. Therefore, in order to obtain a uniform series only ploughs have been treated as agricultural implements.

Data on livestock labour and ploughs require two adjustments. Firstly, no census was held in Bengal in 1935. So figures for this year have been interpolated on the basis of the rate of growth between 1930 and 1940. The second adjustment is for the year 1945 when only the all-Bengal figures were published. The regional figures for this year have been estimated on the basis of the percentage distribution of livestock labour and ploughs in 1940.

Statistics on livestock population and agricultural implements were said to have been collected by the village panchayets.¹ In the light of the picture that emerges with regard to the crop statistics discussed earlier it is difficult to say whether the panchayets were really the primary source. However, since the same agency may have been responsible for compiling the data it would seem that the margin of error was more or less the same over the entire period.

5.6 OCCUPIED HOUSES

Data on 'occupied houses in the villages' are available from the Decennial Population Censuses. In the Census Reports no reference is made to the size, type and uses of these houses. Thus, ideally these data require three adjustments, but actually no adjustment is possible. The difficulty with regard to the different uses of the rural houses arises from the very nature of the problem of including houses as an item of capital stock. In a peasant agriculture it is not possible to estimate the number of houses used for purely residential purposes as against those used for 'productive' purposes only. For it is common knowledge that the same house may be used by a cultivator partly for residential purposes and partly for storing crops. In many cases it so happens that a portion of a house is shared by cattle. These considerations clearly preclude the possibility of making an estimate of the proportion of rural

¹ *Cattle Census Reports*, p. 1.

houses used for production purposes only. Changes in the types and sizes of houses at different points of time are less difficult to ascertain, but the relevant type of data are not available from the census reports. In a stagnant economy characterised by a fast rate of population growth it is very likely that there were considerable changes in the types of houses over a period of 25 years. Therefore, it would seem that the estimates presented in this chapter have to be interpreted with considerable reservation.

5.7 AVAILABILITY OF PRICE STATISTICS

It has been pointed out earlier that for the purpose of aggregation of the different items of capital stock these are weighted by their market prices. Such prices were compiled by the Banking Enquiry Committee¹ for all the categories included in this study except houses. How far are these price statistics reliable? This question is important, because prices of all these items differ widely not only in relation to their quality and position but also between different points of time within the same year. Statistics available from this source were not collected on the basis of any scientific procedure. As against this, price statistics available from an alternative source² were collected from randomly selected representative farms over a period of three years. It is true that these data refer to a later period and only to the West Bengal districts. But it would seem that the bias introduced by these limitations, if any, would be less marked. Therefore, data available from this latter source are used for purposes of aggregation. Weights given to the different items on the basis of these statistics are as follows: land: 0.625; houses: 0.196; work animals: 0.035; ploughs: 0.011.

5.8 AGRICULTURAL LABOUR

Data on agricultural labour present two problems. The first problem, which is more or less common to all the underdeveloped countries, is caused by imperfection in the occupational specialisation in these countries. In advanced economies the worker is engaged full-time in his listed occupations. But in the underdeveloped countries many of the cultivators generally move within a wide range of occupations in accordance with changes in prospective net advantages. These activities include various forms of small-scale trading, the supply of transport services and the provision of personal services generally.

¹ *Report of the Bengal Provincial Banking Enquiry Committee* (Calcutta, 1930), Chapter v, p. 26.

² Government of India, *Studies in the Economics of Farm Management in West Bengal* (Delhi, 1963), p. 52.

Many of them may remain idle during the slack season. Such an imperfect specialisation of labour may greatly affect the meaning and significance of occupational statistics.¹ It is, however, clear that though imperfect occupational specialisation affects the usefulness of the calculated magnitude of total labour supply at a particular point in time we may still gain some idea about time-trends if it can be assumed that the degree of imperfection remains more or less constant over time. This brings us to the second problem referred to earlier. Can it really be assumed that the degree of imperfection was more or less uniform in Bengal during the period under review?

The Census returns of 1931 showed a reduction of nearly two million in the total work force in Bengal and most of this decline was recorded in the category 'Exploitation of animals and vegetation'. It was only in the four occupational groups of 'Public force', 'Professional and liberal arts', 'Persons living on their income' and 'Insufficiently described occupation' that no reduction in labour was recorded.² The number of people engaged in different occupations was not calculated in 1941. Instead, some estimates of the labour force in agriculture were made on the basis of information obtained from every fiftieth slip from the census materials. Calculation on the basis of these estimates shows that the volume of agricultural labour remained at the 1931 level, though population increased by 5 million.

The Census Report of 1931 recorded some differences in the proportion of people belonging to different age-groups.³ It is unlikely that these differences meant a marked increase or decrease in the volume of the total work force. Therefore, it may be assumed that if a uniform mode of classification had been followed the rate of change in the volume of the labour force in 1931 would have been more or less the same as in the total population. But it is clear that no uniform criterion was followed. Thus, while the classification in 1921 was simply between 'actual workers' and 'dependants', that of 1931 was between 'workers', 'working dependants' and 'dependants'. This change in the mode of classification must be treated as of fundamental importance. This is because the phrase 'working dependants' was so narrowly defined that a large number of persons who would have been returned as 'workers' by the standard adopted in 1921 were returned as dependants pure and simple in the Census of 1931.⁴ It was admitted in the Census Report that the figures for 'earners' may be taken in general as being reasonably accurate, but in

¹ For a more detailed treatment of this problem see P. T. Bauer and B. S. Yamey, *The Economics of Underdeveloped Countries* (Cambridge, 1957), Ch. III.

² *Census of India, 1931 Vol. v Bengal and Sikkim, Part. 1* (Calcutta, 1933), p. 260.

³ *Ibid.*, Ch. IV.

⁴ For details see B. G. Gate, *Changes in the Occupational Distribution of Population* (New Delhi, 1940).

view of this defect it is correct to say that the figures for 'working dependants' are considerably on the low side.¹ Thus it may be safely concluded that the work force involved in agriculture did not really decline in 1931.

In view of these considerations it is clear that the size of the agricultural labour force as shown in the Census Reports of 1931 and 1941 is not comparable with the size calculated in 1921. This means that data on agricultural labour need to be corrected if we are to gain some idea of the trends in the capital/labour and land/labour ratios. Therefore, in the present work it has been assumed that the ratio of the agricultural labour force to the total population in 1931 and 1941 was the same as in 1921. Evidently such a method of correction is somewhat crude because, though it may be confidently asserted that the total volume of agricultural labour increased with the growth of population, it is risky to assume that the rate of increase was the same. The findings on the trends in the capital/labour and land/labour ratios have to be interpreted with reference to this limitation of the data on agricultural labour.

It was admitted by the Census Commissioners of both India and Pakistan that in 1941 there was an overcounting of 5.4 million in the figures on total population.² Accordingly the all-Bengal figure has been deflated. To facilitate comparison the size of the labour force shown in the Census Report of 1921 has been assumed to represent the number in 1919/20 when the first cattle census was conducted.

5.9 METHOD OF PRESENTATION

On the basis of the data discussed in the preceding pages indexes of physical capital assets are presented for the period from 1919/20 to 1944/45. In all, 12 different indexes are presented for different combinations of capital assets and their relationship with labour, land and output. Indexes C1 to C4 refer respectively to the four items of land, houses, animal labour and ploughs. Index C5 represents the total volume of physical capital. Index C6 refers to all categories of capital excluding land. Land was the most important item and, therefore, this procedure has the merit of showing the combined trend in houses, livestock labour and ploughs. Similarly, in order to isolate the influence of both land and houses index C7 has been constructed only on the basis of the data on draught animals and ploughs. Indexes C8 and C9 respectively measure the changes in the availability of draught animals and implements per head of labour and per unit of cultivated land. Finally

¹ *Census of India, op. cit.*, p. 261. 'Working dependants' was not anywhere reported in the two occupational sub-groups of 'cultivating owners' and 'tenant cultivators'.

² *Census of India, 1951, Vol. I, Part I-B* (Delhi, 1955), p. 104.

changes in the capital/output ratio are shown in indexes C₁₀ to C₁₂. These indexes are constructed for analysis of the trends in all the individual quinquennial periods. To facilitate comparison for the six quinquennia as a whole the average quinquennial rates are presented at the beginning.

5.10 OVERALL RATES OF CHANGE

Percentage rates of change in the different items of capital assets for all the quinquennial periods taken together are presented in Table 5.1. The total volume of farm capital shows an average quinquennial increase of 2.6 per cent in the unrevised series and 1.2 per cent in the revised series. It is needless to mention here that the entire difference in the two series is due to the revision of acreage statistics for the last six years. As it is believed that the revised series is more reliable it is clear that the rate of increase in durable physical assets involved in Bengal agriculture was much lower than the growth of total labour force. The picture further deteriorates when the trends in the individual categories are analysed as it becomes clear that almost the entire increase in the total volume was due to the expansion of acreage under cultivation. The number of occupied houses in the rural areas increased at a

faster rate than the growth of population, though it is not known whether this was at the cost of change in the type and size of houses. Conversely, the number of work animals and ploughs declined during the period as a whole. These varying directions and rates of change in the different categories of durable assets and their relationship with the growth of labour force raise a number of questions of basic importance for the agrarian economy. However, before we proceed to deal with these questions the main features of the changes at the regional level and the trends in the individual quinquennial periods may be pointed out.

So far as the total volume of physical capital is concerned, Chittagong Division appears to have the closest resemblance with the all-Bengal rate of increase. The four other regions belong to two opposite extremes. Thus, while the rate was much higher in Presidency and Dacca Divisions, it was much lower in the two other regions.

As to the trends in the individual series the general picture is the same

as indicated by the provincial average, i.e. in all the regions the rates of change in the total volume almost wholly reflect the trends in acreage under cultivation. Once again, the rate of increase in the number of occupied houses was impressive in all the regions except for Presidency Division. On the other hand, this latter region has the lowest rate of decline in work animals. Among the four other regions the rates of decline were highest in Burdwan, Rajshahi and Chittagong. The all-Bengal picture with regard to the trend in ploughs was representative of only three regions – Presidency, Burdwan and Rajshahi. In the two other Divisions the number of ploughs increased, though at low rates. These differences in the trends of work animals and ploughs at the regional level would indicate that at least a part of the animal labour in Presidency Division and ploughs in the other regions became underemployed or unemployed during the period under discussion. But from the explanation which is attempted in a later section it would seem that this may not necessarily have been the case.

5.11 TRENDS IN THE QUINQUENNIAL PERIODS

The overall trends in the different categories discussed above were not, however, the same in all the five individual quinquennial periods. Thus, during the first six years when the prices of agricultural produce had made a considerable recovery there was some increase in the number of animals, houses and ploughs. Conversely, the acreage under cultivation was below the level of the base period (Table 5.2). The obvious result of this drop in land – the most important item – was that the total volume of physical assets was lower than in 1919/20. The provincial trends in all the individual series were representative of almost all the regions.

The acreage under cultivation expanded during the years from 1926/27 to 1929/30, though this was yet to exceed the level of the base period (Table 5.3). The increase in the number of houses (C₂) continued during these years, but again at a low rate. The trends in Series C₇ are particularly important as these point out the timing of the decline in numbers of work animals and ploughs which continued during the next decade. Prices of agricultural produce during these years were higher than in the preceding quinquennium. The decline in C₃ and C₄ in spite of this relative prosperity stands in sharp contrast to the experience of the first six years. At the regional level it was only in Dacca that the trends in draught animals and ploughs were opposite to those indicated in the provincial average.

During the third quinquennium there was an acceleration in the rate of increase of houses (C₂), but land still remained at the level of the preceding quinquennium (Table 5.4). The continuation of the decline in animal labour

Capital in agriculture

and ploughs during these years has to be interpreted with reference to the fact that no census was held in 1935 and the relevant data have been interpolated on the basis of the rates of change between 1930 and 1940. In spite of the possible error in these two series (C₃ and C₄) it may, however, be asserted that during the 15 years from 1919/20 there was hardly any change in the total volume of durable physical assets involved in Bengal agriculture. The provincial trends with regard to the different categories were once again characteristic of all the regions except in the case of land.

As to the acreage under cultivation the fourth quinquennium was a turning-point as it was during these years that for the first time land exceeded the level of the base period (Table 5.5). The obvious result of this expansion – characteristic of almost all the regional units – was that for the first time the total volume (C₅) was higher than in the base period. Among the three other categories the rate of increase in the number of houses slowed down. Conversely, the rate of decline in work animals was higher than in the preceding quinquennium. There was a considerable recovery in the price-level of agricultural produce during these years. The decline in C₃ and C₄ in spite of this recovery indicates the revival of the inverse relationship between price and these two categories which first started in the late 1920s.

Bengal agriculture 1920–1946

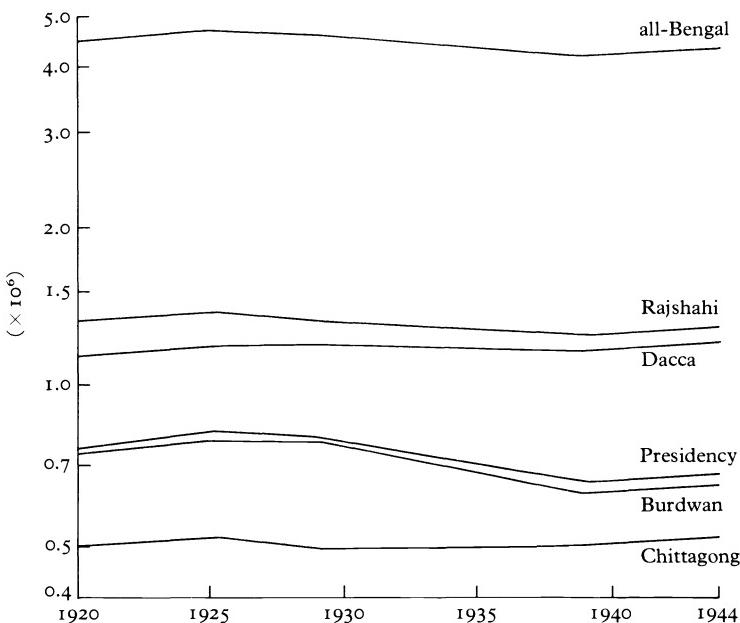

FIGURE 5.3 Ploughs in the quinquennial periods (log scale).

Trends in acreage during the last five years differ widely between the revised and unrevised series (Table 5.6). The decline in the revised series has to be understood with reference to the nature of the revision of acreage statistics. Among the three other component units, the decline in the number of ploughs during the years 1926/27 to 1939/40 was now reversed, though the actual number was still below the level of 1919/20. There was a considerable loss of work animals during the famine years.¹ It would, therefore, seem likely that the trend in the number of work animals would also be positive during this quinquennium. Prices of agricultural produce radically increased after 1940. This would indicate that the inverse relationship between price and the series C₃ and C₄ which was characteristic of the second and the fourth quinquennia had now changed.

To summarise the trends in the individual quinquennial periods, expansion of acreage seems to have started in the fourth quinquennium. Numbers of houses increased all throughout the period, though at varying rates. Conversely, the number of draught animals and ploughs declined during the years 1926/27 to 1939/40.

5.12 RELATION BETWEEN LABOUR AND CAPITAL

How do we explain this decline in ploughs and draught animals (series C7)? This question is of particular importance as it is believed that an exogenous increase in the labour force engaged in agriculture provides an impetus for the growth of capital and this impetus works through the complementary relationship between labour and capital in crop production.¹ Since there was a substantial increase in the volume of agricultural labour in Bengal during the period under review, according to this view the number of ploughs and the quantity of animal labour should have also increased. But in the light of the available data it seems that the process was just the reverse.

In view of the lack of data on working capital, complexities in estimating physical assets and the nature of the data on agricultural labour it is difficult to be reasonably confident whether the decline in the capital/labour ratio was as high as 24 per cent (Table 5.7). However, it may be safely asserted that the underlying trend was one of decline. This decline in the capital/labour ratio indicates that by 1944/45 a considerable part of the total labour force in Bengal agriculture had become underemployed or un-

employed. However, if it is believed that there was unemployment or under-employment at the beginning of the period under review, these trends would indicate that the problem had become more acute in 1944/45. It is needless to mention here that this finding is quite consistent with the widely-held view that underdeveloped agriculture is characterised by the presence of a considerable stock of surplus labour.

What then remains of the thesis that since there is zero substitutability between labour and capital the increased supply of labour will stimulate an autonomous increase in farm capital (series C7)? The purpose in raising this question is not to doubt the validity of this relationship in an underdeveloped agriculture, but to point out that this complementary may not necessarily lead to an increase in ploughs and animal labour. If it is believed that this view about the impact of zero substitutability between labour and capital is correct, two other assumptions have to be made. From the supply side it has to be assumed that per capita income is constant though population is increasing or, if there is a decline, the deficit is met by an increase in the savings/income ratio, or the greater availability of borrowed funds, or both. From the demand side the assumption will be that along with the increase of labour there is a corresponding expansion of cultivation to new areas or that the marginal productivity of labour on existing land is remunerative, or both.¹

Let us now examine if these are valid assumptions in the case of Bengal; it is convenient to start with the second. We have already seen that there was a marked disparity between the rates of expansion in acreage and the increase in the supply of labour (Table 5.1). The decline which thus took place

¹ It must, however, be recognised that the decline in C7 may have been due to an increase in investments which increased the area under double cropping or in improved seeds or in the construction of additional houses or in all of these items. The purpose is to point out that even if these possibilities are not taken into consideration the hypothesis that the increased supply of labour will lead to an autonomous increase in capital may not be valid.

Capital in agriculture

in the availability of land per head of labour in the agricultural sector is shown in Table 5.8. These trends in the land/labour ratio indicate that though the supply of labour increased there was no demand (induced by a corresponding expansion of acreage) for equipping all the additional labour with ploughs and work animals. In this connection it may be mentioned here that most of the expansion of acreage which took place during these years was due to the increase in double cropping. This is important as it shows that what was needed was not an increase in the number of work animals and ploughs, but the greater intensity in the use of the same ploughs and animal labour during the relatively slack season of the year.

It may, however, be argued that even if there was no corresponding extension of cultivation to new areas the additional labour could have been used on the land already under cultivation and this would have provided an incentive to a growth in farm implements and animal labour (C7). Clearly this argument would assume that the marginal productivity of additional labour was remunerative. In other words, the additional output to be obtained from the employment of additional labour was higher than the extra expenditure required to equip such labour.¹ Obviously it is not possible to say anything definitely as to whether conditions in Bengal during the period under review were so favourable as to fulfil this assumption.

Some idea may, however, be made from the findings of the survey of farm economics conducted in certain west Bengal districts during the three years from 1954/55 to 1956/57. Two features of these findings are of particular interest in the present context. Firstly, as many as 50 per cent of the farms are incurring losses.² Secondly, the use of additional inputs increases yield up to a

TABLE 5.8 *Index of the land/labour ratio*
(1919/20 = 100)

Note: Figures in brackets refer to the revised acreage statistics.

¹ This will be the consideration in the case of self-employed labour. In the case of hired labour the wage will have to be taken note of.

² See: *Survey of Farm Economics* (*op. cit.*), pp. 72-3.

certain point, but this results in lower rates of profits and higher losses.¹ It may be safely asserted that the agrarian economy of Bengal hardly experienced any basic change in the decade following independence. It would, therefore, seem that the significance of these findings holds equally good for the period under review.

However, though the preceding discussion explains why the increase in labour supply did not result in an autonomous increase in series C₇, it still remains to be explained why there should have been a decline. This calls for an examination of the first assumption. This examination is important as in our image per capita income in an underdeveloped economy is low and the long-term trend is one of stagnation, if not decline. In such a situation the very condition (increased supply of labour) which is supposed to provide an impetus to the growth of farm capital (C₇) makes addition to capital stock more difficult. So far as Bengal is concerned, in the absence of relevant data, it is not possible to make any estimate of the trend in per capita income during the period under discussion. As an alternative some idea may be gained from the trend in per capita all-crop output, but this again raises the question of the reliability of crop statistics. However, if we accept these figures for whatever they are worth, it is clear that per capita income was declining. For whereas population was increasing at the rate of 0.8 per cent per year, the rate of increase in all-crop output was only 0.3 per cent per year (0.9 per cent in the unrevised series). This disparity between population growth and crop output indicates how the increased supply of labour is likely to have discouraged (not stimulated) further addition to the capital stock.

Could it be argued that there was an improvement in the availability of borrowed funds? Relevant data are available only on Co-operative Credit (discussed in the next chapter), but these funds accounted for such a small proportion of the total requirements that it is difficult to make any reliable guess about the underlying trend. However, there are three *a priori* considerations which would suggest that the availability of loanable funds declined, particularly from the beginning of the depression period. Firstly, the fact that the per capita income in the agricultural sector as a whole was declining suggests that the proportion of rural families with loanable surplus became smaller.² Secondly, as this section of the rural families are usually more affected by changes in market conditions it would seem that the slump in agricultural prices in the 1930s further aggravated the underlying trend of a decline in loanable funds. Thirdly, working in the same direction may have been the influence of the Money-lenders Act of 1933 and the Agricultural

¹ *ibid.*, pp. 87–90.

² This is obviously on the assumption that the distribution of income among the different classes of rural family remained unchanged.

Capital in agriculture

Debtors Act of 1935. The influence of the second Act under which Debt Conciliation Boards were set up to scale down ancestral debts would seem to have been of particular importance as it came at a time when there was as yet no recovery in the price level. These considerations would suggest that the flow of capital from the non-agricultural sector was also declining.

As already pointed out it is difficult to say how far this decline in series C7 reflects a real drop in the level of total investment in inputs other than land and houses. However, if any conclusion is to be drawn from the available data, it is clear that there was hardly anything in the economy which could allow the increased labour supply to lead to an increase, rather than a decline, in farm implements and livestock labour.

5.13 CAPITAL/LAND RATIO

As a matter of fact it seems that in an under-developed agriculture the best criterion on which to judge the trends in such traditional inputs as draught animals and ploughs is to examine the capital/land ratio. In such an agriculture, where the scope for the extension of cultivation is limited and the increase in labour supply is given, it is the change in the availability of ploughs and animal labour per unit of land under cultivation which is most important. In this respect the picture that emerges with regard to Bengal agriculture is presented in Table 5.9.

During the first six years the capital/land ratio was increasing. This was followed by a decline, which remained low during the second and the third quinquennia and then accelerated during the fourth. During the period as a whole the availability of farm capital (C7) per unit of land declined by 9 per cent in the revised series. The real magnitude of this drop

TABLE 5.9 *Index of the capital/land ratio
(1919/20 = 100)*

| Regions | 1919–20 | 1925–26 | 1929–30 | 1930–34 | 1939–40 | 1944–45 |

Note: Figures in brackets refer to the revised series. Capital in this Table includes only ploughs and work animals.

must have been smaller in view of the fact that most of the expansion of acreage was due to the increase in double-cropping. However, even if this latter aspect is not taken into consideration, it is clear that the disparity in capital/land ratio was much less marked than the decline in capital/labour ratio.

However, the fact that the total number of work animals and ploughs declined in spite of some expansion of acreage raises the question as to whether this had any impact on the yield per acre. It may be recalled here that the yield slightly improved in the first decade. This was followed by stagnation during the next two quinquennia and some drop in the last.

This constancy in yield during the years from 1929/30 to 1939/40 in spite of the decline in farm capital would imply that (a) animal labour and ploughs in this period were of a better quality and/or (b) there was a surplus stock during the initial years so that in spite of the decline in the latter years the intensity of cultivation remained more or less the same or (c) the stock of farm capital was reduced to finance investment in such inputs as improved seeds so that the level of productivity was not affected. As already pointed out it is difficult to say anything definite on the first and the third score. So far as the second possibility is concerned the findings of the survey in the West Bengal districts referred to earlier would indicate that the decline in work animals did not mean a change in the intensity of cultivation, but an improvement in the intensity of capital utilisation — so that productivity per acre did not decline. The high level of unemployment of livestock labour in the various sizes of farms is shown in Table 5.10.

This study may be concluded by a reference to the trends in the amount of capital of various types that have been used over the years to obtain the supply of a unit of agricultural output. Opinions are divided as to the methods of estimating such costs in terms of capital. Thus, capital/output ratios may

be estimated on the basis of both the numerator or denominator being gross or net. For the present purpose the estimates are made on the basis of gross output and gross physical capital. This procedure is clearly suggested by the nature of the available data. Moreover, since the capital/output ratio is a technical relationship gross output becomes relevant. Secondly, the estimates are presented only for all-Bengal. In Table 5.11 index C₁₀ is obtained by dividing index C₅ (aggregate volume of capital) by output. In constructing index C₁₁ only land, and in index C₁₂ both land and houses, are excluded from the stock of capital.

In interpreting these findings it has to be recalled that the output figures for the cattle census years have been estimated, as in the case of acreage data, on the basis of a three years' average centred on those years.

As expected from the quinquennial trends in series C₇ it is clear that the underlying trend was one of decline (index C₁₂) in capital per unit of output. This drop in the number of draught animals and ploughs per unit of output has to be attributed to the various possible changes discussed earlier. However, the picture that emerges when a 'statistical bias' is introduced by the addition of houses to the stock of capital is the reverse – except during the first 10 years the capital/output ratio was increasing (series C₁₁). It has to be recalled here that no adjustment has been made for any possible change in the types and sizes of houses in the rural areas. The quinquennial trends in index C₁₀ are less consistent, but compared to the base year the capital/output ratio was always lower. In other words, the aggregate volume of physical capital used to obtain a unit of output was smaller than in 1919/20. However, the total volume of decline in the capital coefficients was very low.

The scope of this study is obviously limited in that it is confined to an analysis of the trends only in durable physical assets involved in Bengal agriculture. It has not been possible either to include such items as working capital and investment in seeds or to relate even the limited number of

TABLE 5.11 *Trends in the capital/output ratio*
(1919/20 = 100)

| Years | Index C ₁₀ | Index C ₁₁ | Index C ₁₂ |
|---------|-----------------------|-----------------------|-----------------------|
| 1919/20 | 100(100) | 100(100) | 100(100) |
| 1926/27 | 96(94) | 100(99) | 101(100) |
| 1929/30 | 94(90) | 97(94) | 95(92) |
| 1934/35 | 95(92) | 102(99) | 94(91) |
| 1939/40 | 103(94) | 108(100) | 93(86) |

categories to the trends in per capita income and total savings. Moreover, the available data have certain limitations. However, if the findings presented above are believed to be of some significance the following conclusions may be drawn. Of the four categories selected for this study the acreage under cultivation and the number of houses increased. The trend in the former category substantiates our assumption that in an under-developed agriculture most of the increase in capital formation would be in such a form as would expand the productive acreage, and if the scope for the extension of cultivation to new areas is limited such increase would be achieved through an increase in the proportion of double cropped area. The increase in these two items was accompanied by some decline in draught animals and ploughs. The rate of increase of the total volume of durable assets was far below the growth of labour force. Secondly, the decline in the number of work animals does not seem to have had any adverse impact on the productivity per acre of land. Thirdly, this would imply that either there was a surplus stock of animal labour and ploughs at the beginning of the period under discussion or a slight shift towards the use of better inputs.

6

AGRICULTURAL CREDIT AND THE CO-OPERATIVE CREDIT MOVEMENT

The purpose of the present chapter is to evaluate the performance of the Co-operative Credit Movement during the period under review (1920–47). However, in order to place the movement in its proper perspective, we start with a brief reference to some general issues related to agricultural credit. Finally, the opinions of some individual authors and committees of enquiry about the limited success of the Co-operative Credit Movement are briefly reviewed.

6.1 THE GENERAL BACKGROUND

A proper system of credit is of as basic importance to agriculture as it is to industry. But agriculture has certain distinctive features which place it in a disadvantageous position as against industry in respect of the availability of finance from the usual credit agencies. First of all, the scale of production in agriculture is small. 'While other industries tend to become concentrated in units of ever increasing size, agriculture remains scattered, individualistic, small-scale and chaotic.'¹ The problem is further complicated by the simultaneous presence of production for domestic consumption and the market. In these conditions a large part of the working capital which the cultivators need has the character of being related to their consumption rather than to production. Secondly, the risks and uncertainties involved in agricultural production are greater than in manufacturing industry, as success in agriculture depends on factors outside the control of the cultivators. A third distinctive feature of agriculture is that agricultural products are often perishable or of such a nature that they cannot be properly stored. Lastly, agricultural production involves a longer time scale than does industrial production – sometimes the cultivators have to wait a year for their harvests. They cannot switch over to an alternative crop in response to a shift in prices once the land has been sown with a particular crop. As a result of

¹ *Report on the Indian Central Banking Enquiry Committee* (Calcutta, 1931), Vol. 1 (Majority Report), p. 45.

these factors the cultivators cannot make use of capital with the same degree of efficiency as does industry generally.¹

However, it is not only the internal weakness of agriculture which prevents the cultivators from attracting the services of the external mechanism of banking. By its very nature agriculture is rural, whereas these external establishments are urban in respect of location, preferences and the interests of the individuals who share the power of dispensing credit. As a result agricultural credit is usually the least organised.²

The Indian conditions were not such as to make the situation any different either. In the nineteenth century the 'opening up' of the country to wider commercial intercourse with the world market marked the advent of a cash economy in the rural areas on a much larger scale than before. The use of money assumed greater prominence even in areas or among sections of population which remained relatively unaffected by the spread of commercialisation. But as the credit agencies which grew up in the changed circumstances almost exclusively catered for the needs of the export trade and domestic industries, the rural areas remained cut off from the organised sources of finance. Thus, with the functional mechanism of an economic structure remaining incomplete, a vacuum was created and this was filled by the money lenders.³

If we look at the problem of agricultural credit in India in this way, it is clear that the money lenders did in fact fulfil an indispensable economic function. But the price they charged for their services was very high and they often indulged in malpractices. Thus, during the period under review interest on loans to agriculturists given on the security of land generally varied from $18\frac{3}{4}$ per cent to $37\frac{1}{2}$ per cent per annum. Interests on loans given without security were much higher, sometimes as high as 300 per cent per year.⁴ Why was the rate of interest so high? The determination of interest rates is one of the most complex theoretical issues in economics. But evidently this question has an important bearing on the problem under investigation in this

¹ Incidentally it may be pointed out that it is for some of these reasons that the cultivators need credit.

² For further elaboration of these aspects see Reserve Bank of India, *All-India Rural Credit Survey*, Vol. II (Bombay, 1954), pp. 151–5. Henceforth referred to as *Credit Survey*. See also *Central Banking Enquiry Committee*, *op. cit.*, pp. 44–54.

³ Throughout this study money lenders are meant to include, apart from the residential and itinerant ones (Mahajans, Pathans and Kabulis), persons who had other occupations, but also lent money such as landlords, merchants and pensioners. It is not suggested here that the origin of money lenders was due or associated with the spread of commercialisation. As a matter of fact money lending seems to have been a much older institution. See, *Bengal Provincial Banking Enquiry Committee* (Calcutta, 1930), Vol. I, pp. 170–80. Henceforth referred to as *Banking Enquiry Committee*.

⁴ *Banking Enquiry Committee*, p. 198.

chapter. Therefore, a brief reference needs to be made to some of the basic issues even though this may mean an oversimplification of a complicated problem.

Economists distinguish between net ('pure') and gross rates of interest. The former is the rate which would emerge if there was perfect competition among the borrowers and the lenders. Gross interest is what is meant by interest in ordinary use, the amount actually paid by the borrowers. Thus, while net interest is that portion of gross interest which is simply paid for the use of capital in competitive conditions, gross interest includes, apart from net interest, the cost of management, a premium for risk and monopoly profits.

According to non-monetary theory, rates of interest are determined, on the demand side, by the marginal productivity of capital. In an underdeveloped agriculture where the supply of capital is scarce in relation to the other factors of production, investment in inputs like fertiliser, pesticides, improved varieties of seeds, are highly productive. But it is generally held that the major part of borrowings is spent for consumption purposes.¹ Secondly, it is true that a part of the capital is directly used for productive purposes, but investment in traditional factors hardly enables the borrowers to increase the existing low level of productivity. It would, therefore, seem to be fairly clear that the high rates of interest in the underdeveloped agriculture are not determined by the marginal productivity or efficiency of capital.

According to monetary interest theory interest is not the price paid for saving, but the charge made for parting with liquidity. In a poor agriculture the liquidity preference is very strong and it is believed that the 'liquidity complex' is one of the reasons for the high level of interest rates. The findings in India that the rates of interest are higher in areas where a subsistence economy prevails strengthen this opinion.² But again this does not explain why even in the more monetised and commercialised areas the price of borrowed funds is so high.

From these considerations it is fairly clear that the high price of capital in the rural areas represented gross interest.³ It is not possible to estimate the

¹ According to the findings of the *Credit Survey* (Vol. I, Part I, pp. 260–321) 37 per cent of the borrowings were for expenditure on the farm and 50.2 per cent for family expenditure. However, it is found that in most cases it was capital expenditure which was the most significant variable (explaining 69 per cent of the variations) affecting the demand for credit. For details see, Dr S. Ghatak, *Rural Money Markets in India* (unpublished PhD thesis University of London, 1972), pp. 75–80.

² *Credit Survey*, Vol. II, pp. 190–6.

³ It is believed that net rate may not account for more than a quarter of the gross rate prevailing in the rural areas. See V. T. Naidu, *Farm Credits and Co-operatives in India* (Bombay, 1968), p. 145.

extent to which each of the three components of gross interest – monopoly profits, premium for risk and administrative cost – was responsible for the high price. However, there is evidence to show that the first two factors were at work. Firstly, it was pointed out to the Bengal Banking Enquiry Committee that the rates of interest were lower in areas where Co-operative Credit Societies were formed.¹ This would clearly indicate how the failure of the regular financial establishments to fulfil certain essential functions left the money lenders in a strong position to take advantage of the monopoly control they enjoyed of a scarce factor (capital) in the rural areas.

Secondly, the rates of interest on secured loans were much lower than in the case of unsecured loans. Such a pattern would indicate that a part of the high rate of interest represented a premium for risk.² However, this clearly conforms to what would be expected in a poor agriculture. In essence the nature of the security depends on two factors: (a) the capacity of the borrowers to earn an income beyond the basic needs of subsistence which will determine their ability to meet interest charges and eventually to repay the loan, and (b) the market value of the asset pledged as security should it be necessary to acquire them because the borrowers cannot meet their obligations.³ In both these respects the specific conditions in Bengal were unfavourable to the borrowers. As the larger section of the rural population lived at the margin of subsistence their repaying capacity must have been poor. As to land, which was the best asset to be offered as security, there were many peasants who were landless. On the other hand, the sale price of land which the owner–occupier could obtain was depressed as the landlords were entitled to a transfer fee. It may be argued that since the money lenders had a monopoly in the rural areas they could charge a higher price than otherwise possible,⁴ but it cannot be denied that considerable risk was involved in lending to borrowers with inadequate credit and this led to money lenders charging a premium. The preceding discussion would suggest that it was not only monopoly profits as such, but the low level of per capita production of

¹ *Banking Enquiry Committee*, p. 136. The experience has been found to be the same in India. For details see *Credit Survey*, Vol. II, pp. 190–6.

² *Banking Enquiry Committee*, p. 198. Different rates of interest on secured and unsecured loans were provided for under the Bengal Money-lenders Acts of 1933 and 1940. In India it has been found that an estimated four fifths of the debt owed to the professional and agricultural money lenders was unsecured. See *Credit Survey*, Vol. II, p. 169. According to the findings of Dr Ghatak (*op. cit.*, p. 163) it seems that most of the cost of credit in the rural areas was due to the high risk and uncertainty involved in lending to small-scale peasant producers.

³ For a useful discussion particularly on this aspect of the problem see, A. Bottomley, *Factor Pricing in Underdeveloped Rural Areas* (London, 1970), Chapter 12; Food and Agricultural Organisation (UN), *Agricultural Credit in Economically Underdeveloped Countries* (Rome, 1959), pp. 30–2.

⁴ *Report of the Agricultural Finance Sub-Committee* (Delhi, 1945), p. 59.

the borrowers which accounted for the high rates of interest in the agricultural sector.

For a long time during the nineteenth century the policy of the government was one of non-interference with these forces in the rural economy which pushed up the price of credit. Such a policy was embodied in the Promulgation of 1855 which provided that 'in any suit in which interest is recoverable the amount shall be adjudged or decreed by the court at the rate (if any) agreed upon by the parties' and in the absence of any such agreement 'at such rate as the court shall deem reasonable'.¹ The evils which followed in the subsequent years, particularly in the form of land transfer from the borrowers, led to the passing of protective legislation in two Provinces – the Deccan Agriculturists' Relief Act and the Punjab Land Alienation Act. Action taken at the all-India level, though in principle more positive than the protective legislation, fell far short of the establishment of an Agricultural Bank which was being discussed for a long time.² This was the Land Improvement Act of 1883 and the Agriculturists' Loans Act of 1884 under which the Provincial Governments were allowed to advance loans to the cultivators. But the effectiveness of these two enabling Acts was hardly better than that of the protective legislation – the supremacy of the money lenders remained undisturbed and the transfer of land also continued.³ At the turn of the present century it was realised that this legislation would have to be supplemented by more organised efforts for the supply of credit at a reasonable price and the result was the inauguration of the Co-operative Credit Movement under the Credit Co-operative Societies Act of 1904. The underlying assumption seems to have been that this arrangement, by offering effective competition, would compel the money lenders to reduce the rate of interest and thus solve the problem of rural indebtedness.

The Act of 1904 provided for the formation only of credit societies in both the urban and the rural areas. The rural societies were to have unlimited liability and the urban societies were free to opt for either limited or un-

¹ Cited by the *Banking Enquiry Committee*, p. 164. Before 1855 the statutory limit on the rate of interest as provided for under the Regulation of 1774 was 12 per cent.

² For a discussion on the background of these Acts see I. J. Catanach, *Rural Credit in Western India, 1875–1930* (University of California Press, 1970), pp. 10–32; see also T. R. Metcalf, 'The British and the Money-Lenders in the Nineteenth Century India', *Journal of Modern History*, Vol. XXXIV, No. 4 (1962), pp. 390–7. The problem of agricultural indebtedness in Bengal in the second half of the nineteenth century is examined by B. B. Chaudhuri, 'Rural Credit Relations in Bengal, 1859–1885', *Indian Economic and Social History Review*, Vol vi, No. 3 (1969), pp. 203–57.

³ For the effectiveness of the Deccan Act see Catanach, *op. cit.*, pp. 25–6; for the Land Alienation Act see, M. L. Darling, *The Punjab Peasant in Prosperity and Debt*. Fourth edition (London, 1947), pp. 197–200; loans advanced in Bengal under the Loans Act and Land Improvement Act averaged 6.24 lakhs per year during the period from 1919 to 1928. For details see *Report on the Land Revenue Administration of the Presidency of Bengal* (annual).

limited liability. However, in reality the main emphasis was on the formation of agricultural credit societies. This defect of confining the scope of co-operative activities only to a particular field was soon realised as societies with other purposes began to be formed. Secondly, the Act of 1904 did not provide for the formation of any central agencies, banks or unions. These deficiencies were remedied by the Co-operative Societies Act of 1912.¹ However, the pace of progress in the immediately following years both with regard to the formation of Primary Societies and Central Banks remained slow. Thus, in 1920 there were only 5.8 thousand Primary Societies and 71 Central Banks in Bengal.

The Primary Societies obtained their capital from the following sources: (a) Share Capital paid up by the members, (b) a Reserve Fund created out of profits, (c) deposits from the members and loans from (d) Central Banks, (e) non-members, (f) government and (g) other societies. Funds from the first three sources formed the owned and those from the last four formed the borrowed capital of the Co-operative Societies.

Though the scope of the Act of 1904 was widened to include societies for purposes other than credit, the main character of the Co-operative Movement in the Province, as in other parts of India, remained essentially agricultural. Thus, out of a total of 41.0 thousand Primary Societies even in 1943/44 as many as 35.7 thousand were agricultural credit societies. Evidently this high proportion underlines the importance which was assigned to the problem of agricultural credit.

The remaining part of this chapter is devoted to an analysis of the achievements of the Co-operative Credit Movement during the period from 1920 to 1944. The method of presentation is similar to that for agricultural output. Trends in the different sides of the Movement – the number of societies, membership, working capital, etc. – for the period as a whole and the quinquennia are presented for all-Bengal and the five regions. The quinquennial trends are once again indicated by index numbers and for this purpose 1920 is taken as the base year. As a matter of fact the fourth period comprises only four years, but for the sake of convenience this is also referred to as a quinquennium.

6.2 SOURCES OF STATISTICS

All the data relating to the different categories of Co-operative Societies are available from the *Report on the Working of the Co-operative Societies in*

¹ For a discussion on the background and the development of the Co-operative Movement see, Catanach, *op. cit.*, pp. 32–55; E. M. Hough, *The Co-operative Movement in India* (Bombay, 1959), pp. 40–51.

Bengal,¹ and the series is available for the period up to 1943/44. Statistics obtained from this series required two adjustments. Firstly, from 1934/35 'other funds' were separated from the Reserve Funds. Therefore, in order to make the series uniform for the whole period the two items have been added up for the period from 1934/35. Secondly, for the year 1941/42 only the all-Bengal statistics are available. Therefore, the regional data for this year has been calculated on the assumption that the rates of decline or progress were the same in all parts of the Province.

6.3 THE TOTAL NUMBER OF SOCIETIES AND MEMBERSHIP

The role of the Co-operative Credit Movement may be evaluated in its two aspects – external and internal. The former relates to the proportion of total borrowers among the cultivators covered by the Primary Societies. The latter includes such issues as the proportion of borrowings of the members from Co-operatives in their total borrowings, efficiency of repayment and the proportion of owned capital to the total working capital.

As to the external side data are available on the number of Societies and their membership. During the period as a whole the number of Societies at the all-Bengal level increased at the rate of 7.8 per cent per year (Table 6.1) and this was characteristic of almost all the regional units. This represents an increase of 29.9 thousand Primary Societies from 1920 to 1944. Trends in the quinquennial periods show that after a sharp expansion during the second quinquennium the rate of expansion slowed down during the next two periods. This was due to the severe strain imposed on the agrarian economy by the depression and the consequent liquidation of a considerable number of Societies during the years from 1932/33 to 1935/36. Moreover, a policy of consolidation as against expansion was pursued by the Co-operative

TABLE 6.1 *Annual percentage rates of increase and quinquennial index of Societies (1920 = 100)*

| Regions | Rate of increase | 1920-24 | 1925-29 | 1930-34 | 1935-38 | 1939-44 |
|------------|------------------|---------|---------|---------|---------|---------|
| All-Bengal | 7.8 | 128 | 264 | 346 | 371 | 611 |

| Chittagong | 7.9 | 140 | 308 | 407 | 428 | 676 |

¹ Annual publication of the Government of Bengal. Henceforth referred to as *Annual Report*.

Department from 1929/30 to 1931/32. The marked expansion during the last five years, more or less equally witnessed in all the regions, was due to the formation of a large number of Societies for the distribution of loans under a revised scheme discussed later.

The role of the Co-operative Movement in its external aspect obviously does not depend only on the formation of new Societies, but also on the average size of membership and its long-term changes. In this respect two important features may be pointed out. Firstly, the size of membership per society remained small – only 26 at the all-Bengal level. Secondly, the annual rate of expansion in membership for the period as a whole was lower than in the formation of new societies (Table 6.2). The only exception to this general pattern was Chittagong Division. The discrepancies between the number of societies and membership which thus took place in the five quinquennia are presented in Table 6.2. Apart from its more important implications noted later, these discrepancies meant that per capita administrative and maintenance expenditure was increasing over time.

6.4 PROPORTION OF BORROWERS COVERED BY CREDIT SOCIETIES

We now turn to the question of what proportion of the total borrowers in the agricultural sector was covered by institutional credit. This involves an estimation of the total number of agricultural families in the quinquennial periods and the proportion of families borrowing from different sources. The unreliability of the census returns of 1931 and 1941 on the total labour force engaged in agriculture has been pointed out earlier.¹ Therefore, for present

¹ Chapter v, pp. 139–41.

purposes it is assumed that the proportion of agricultural labour to the total population as returned in the Census Report of 1921 was the same in the subsequent years. What proportion of these families (assumed to be represented by the quantity of labour) may be said to have been in need of borrowing? No such information is available for the period under review. This problem may, however, be resolved by assuming that the proportion of borrowing families in 1951 in certain districts of West Bengal was representative of all the regions of Bengal during the period under consideration.¹ On this basis it seems that the proportion of borrowing families covered by the Co-operatives for the period as a whole was only 6.4 per cent at the all-Bengal level (Table 6.3).

The picture does not materially improve even if account is taken of only the last quinquennium, when the Co-operative Movement had completed four decades of its existence. The vast majority of the borrowers still remained outside the scope of institutional credit. The variations at the regional level have to be understood with reference to the fact that the proportions of agricultural families to the total families and the percentage of families in need of borrowings have been assumed to be uniform.

6.5 LOANS ADVANCED

The failure of the Credit Movement stands out more prominently when we examine its internal aspect. Thus, while both the number of Societies and membership were increasing the total amount of loans advanced to the members declined (Table 6.4). In other words the increase in membership was accompanied by an almost corresponding drop in the availability of average loans per member. At the all-Bengal level the only exception to this

TABLE 6.3 *Percentage of borrowing families covered by the Co-operatives in the quinquennia*

general pattern was the experience during the relatively prosperous years from 1925 to 1929. Conversely the loan operations came to a virtual stop from the beginning of the depression period. During the last five years the Provincial Government advanced financial assistance to revitalise the Credit Movement but as the proportion of overdue loans continued to increase these advances could hardly improve the situation as regards the availability of average loans per member.

The more important question that has to be asked in connection with the loan operations of the Primary Societies is: to what extent did these loans advanced by the Credit Societies meet the needs of the members? No information is available from the Annual Reports as to the amount received per borrowing member. In view of this difficulty, together with the fact that no estimate of the total borrowings from all sources is available, it is not possible to say anything definite on this question. Some idea may, however, be gained from the proportion of loans advanced by the Primary Societies to the total short-term and medium-term requirements of an agricultural family as estimated by the Banking Enquiry Committee.¹ On this basis the total credit requirements of the average number of members for the five years ending 1928/29 amount to Rs. 59.2 millions, but the amount actually paid by the Credit Societies during this period accounted for only 24 per cent. In other words, institutional loan amounted to only 1.3 per cent of the total borrowing needs of the agricultural sector.

6.6 TRENDS IN REPAYMENT

The efficiency with which the members repaid their loans may be judged by the extent of overdue loans. For the purpose of analysis we have data on

¹ The *Banking Enquiry Committee* estimated that per family requirements amounted to Rs 160. For details see pp. 76–82.

loans repaid every year, the amount outstanding and overdue. All loans outstanding at the end of a year were not necessarily due at that time as many loans were granted for more than one year. This need not be taken into consideration when analysing the overdue loans. If the overdues as a percentage of the total outstanding were increasing it may be assumed that the borrowers were not efficient in repayment.

The annual rates of increase in overdue loans for the period as a whole and its proportion to the total outstanding loans in the quinquennial periods are presented in Table 6.5. In view of the fact that the high proportion of overdues constituted the most fundamental weakness of the Primary Societies a fuller examination of the relevant factors is attempted later. At the present stage three general observations may be made as to the relative position in the different periods. Firstly, except in Chittagong the position even in the relatively prosperous years of the 1920s was not very promising. Secondly, the depression imposed such a strain that even a reduction in the rates of interest and the use of the whole administrative machinery for the collection of overdues could not prevent a deterioration of the situation. Thirdly, in advancing crop loans during the last five years the Provincial Government expected that this would help the recovery of the overdues, but this was not fulfilled. The proportion of overdue loans increased despite the fact that many loans were adjusted against the deposits and the share capital of the borrowers and the legal power of the Co-operatives with regard to the collection of overdues was improved by the Co-operative Societies Act of 1940. Clearly the impact of the famine outweighed the recovery in the prices of agricultural produce.

6.7 WORKING CAPITAL

Data on the working capital of the Primary Societies available from the Annual Reports bring out a redeeming feature of the Credit Movement. At

TABLE 6.5 *Annual percentage rates of increase of overdues and overdues as a percentage of outstandings*

| Regions | Rates of increase | 1920-24 | 1925-29 | 1930-34 | 1935-38 | 1939-44 |
|------------|-------------------|---------|---------|---------|---------|---------|
| All-Bengal | 12.0 | 33.1 | 30.7 | 72.0 | 87.0 | 90.5 |
| Presidency | 12.4 | 43.1 | 38.6 | 77.1 | 90.1 | 93.2 |
| Burdwan | 11.6 | 35.6 | 35.4 | 73.5 | 86.4 | 86.6 |

| Dacca | 12.7 | 34.3 | 27.4 | 70.6 | 85.9 | 92.3 |
| Chittagong | 15.9 | 18.1 | 19.2 | 67.5 | 81.1 | 85.1 |

the all-Bengal level the increase of working capital kept pace with the expansion of membership (Table 6.6). Indeed in three regions – Presidency, Burdwan and Dacca – the position was still better than that indicated by this Provincial average. The quinquennial trends have two main features. The increase in working capital took place during the first 20 years. Secondly, there was a gradual deceleration in the rate of improvement after 1924–25.

6.8 OWNED CAPITAL OF THE SOCIETIES

The owned capital of the Primary Societies increased at a much faster rate than the expansion of membership (Table 6.7). In other words, when the number of members per Society was declining per capita owned capital was increasing. But these trends have to be understood with reference to two reservations. Firstly, for reasons to be discussed later it is doubtful if the increase in one of the components of owned capital – Share Capital – really represents the actual payment made by the members from their own resources.

Secondly, even if this possibility is discounted it is clear that even at the end of the whole period owned capital constituted less than half of the total working capital. Such a picture clearly reflects the failure of an underlying expectation behind the inauguration of the Co-operative Movement, i.e. that through the inculcation of the ideal of ‘self help’ and thrift the members of the Primary Societies would be encouraged to create an adequate fund of their own.

Having thus observed the trends in the owned resources of the Credit Movement at the aggregate level, the relative weights and the rates of change

Note: Figures in brackets refer to the proportion of owned capital to total working capital.

of its three components — Reserve Fund, Share Capital and Members' Deposits — may now be taken up.

6.9 THE RESERVE FUND

The Reserve Fund, which constituted the largest single component of the owned capital of the Primary Societies, was created by the accumulation of a certain portion of the annual net profits and entrance fees.¹ This Fund increased from 15.7 lakhs in 1920/21 to 204.9 lakhs in 1943/44 — representing an annual growth of 12.9 per cent for all-Bengal (Table 6.8). The consequent improvement which took place in the accumulation of this Fund per member actually continued up to the end of the fourth quinquennium. As already mentioned the drop during the last five years was caused by the sudden increase in membership.

It has been argued that the Reserve Funds were illusory in the sense that they were created without making any provision for bad debts.² It is difficult to question the validity of this criticism. But from this it does not seem to follow that net profits were calculated in order to declare dividends on the

TABLE 6.8 *Annual percentage rates of increase and quinquennial index of per member Reserve Funds
(1920 = 100)*

| Regions | Rate of increase | 1920–24 | 1925–29 | 1930–34 | 1935–38 | 1939–44 |
|------------|------------------|---------------|---------------|---------------|---------------|---------------|
| All-Bengal | 12.9 | 116 (14.0) | 151 (14.7) | 295 (23.4) | 421 (32.0) | 261 (35.2) |
| Presidency | 13.6 | 106 | 134 | 295 | 454 | 315 |
| Burdwan | 14.0 | 121 | 145 | 246 | 381 | 388 |
| Rajshahi | 10.2 | 115 | 152 | 273 | 362 | 189 |
| Dacca | 12.9 | 121 | 159 | 310 | 436 | 265 |
| Chittagong | 16.1 | 132 | 231 | 508 | 728 | 435 |

¹ Section 26 of the Rules framed under Section 43 of the Co-operative Societies Act of 1912 provided that in every Society not less than one half of the net profit in any year should be carried to a Reserve Fund until that Fund was equal to one half of the total liabilities of the Societies other than the Reserve Fund and Share Capital. Thereafter not less than one third should be added. If by an increase in the liabilities the proportion of the Reserve Fund to such liabilities was below one half the share of the net profit deposited into the Reserve Fund should be increased to one half until the proportion was restored. Under Section 56(2) of the Bengal Co-operative Societies Act of 1940 one fourth or such a share of the net profit as prescribed was to be credited to the Reserve Fund.

² A. I. Qureshi, *The Future of Co-operative Movement in India* (Bombay, 1947), p. 19.

Agricultural credit

Paid Up Share Capital of the members.¹ For almost all the net profits were added to the Reserve Fund. Thus, while Reserve Funds increased by 189.2 lakhs from 1920/21 the total net profits amounted to only 201.0 lakhs. In other words during a period of 24 years roughly 12.0 lakhs were declared as dividends.

6.10 SHARE CAPITAL OF THE SOCIETIES

Share Capital was first introduced in 1918 though this meant a deviation from the Raiffeisen Principle. It was normally of small values – Rs 10 to 15 each – payable in half yearly or annual instalments. The underlying hope in introducing this practice was that this would not only encourage thrift among the members, but also increase the Societies' financial strength and, by reducing its dependence on outside capital, should make possible lower interest rates to the members. From the published statistics it seems that this expectation was fulfilled as Share Capital increased again at a much faster rate than the expansion of membership (Table 6.9). However, the quinquennial trends show that the improvement in per capita Share Capital continued only during the first 15 years. The sharp drop during the last five years was due partly to the adjustment of overdue loans against Share Capital as noted earlier and partly to the less than proportionate increase in new payments. But as mentioned earlier there is one consideration which suggests that these increases were more apparent than real. The rates of interest on deposits varied between $7\frac{1}{2}$ per cent and 12 per cent in the different regions as against only $6\frac{1}{4}$ per cent on Share Capital. But, despite this, members' deposits increased

TABLE 6.9 *Annual percentage rates of increase and quinquennial index of share capital per member*
(1920 = 100)

| Regions | Rate of increase | 1920–24 | 1925–29 | 1930–34 | 1935–38 | 1939–44 |
|------------|------------------|--------------|--------------|--------------|--------------|--------------|
| All-Bengal | 10.6 | 205 (4.7) | 472 (8.8) | 633 (9.7) | 615 (9.0) | 359 (9.3) |

| Dacca | 11.1 | 224 | 587 | 768 | 724 | 413 |
| Chittagong | 11.2 | 241 | 546 | 729 | 714 | 388 |

¹ J. P. Niyogi, *The Co-operative Movement in Bengal* (London, 1940), p. 21.

at much lower rates. It may be argued that the rural families paid the Share Capital only to join the Credit Societies and once they had done so they did not care much about making further contributions. But the suggestion which seems to be more plausible is that the funds shown as 'Share Capital Paid Up' were not really 'Paid Up' from the savings of the members, but mainly represented a deduction from the capital borrowed from outside sources.¹ It would, thus, seem that the internal strength of the Primary Societies was less satisfactory than appears from the published figures.

6.11 MEMBERS' DEPOSITS

The trends in members' deposits stand in sharp contrast to those in Share Capital and Reserve Funds in that the rates of increase were far slower than the expansion of membership (Table 6.10). This feature was typical of all the regions though the disparity was most marked in Presidency, Burdwan and Rajshahi Divisions. However, the quinquennial trends show considerable variations. Thus, as a matter of fact deposits were increasing at a faster rate during the years from 1924/25 to 1938/39. The improvement in the second period can be easily appreciated as these were relatively prosperous years. But what explains the continuation of this trend during the third quinquennium, which includes the depression years? Part of the explanation seems to lie in the marked improvement during the first two years of this quinquennium when the full effect of the slump in prices was yet to be felt. The sharp drop during the last five years seems to have been due to the haste with which Societies were formed to obtain the crop loans advanced by the Provincial Government, and the effects of the famine.

TABLE 6.10 *Annual percentage rates of increase and quinquennial index of deposits per member*

| Regions | Rates of increase | 1920–24 | 1925–29 | 1930–34 | 1935–38 | 1939–44 |

Agricultural credit

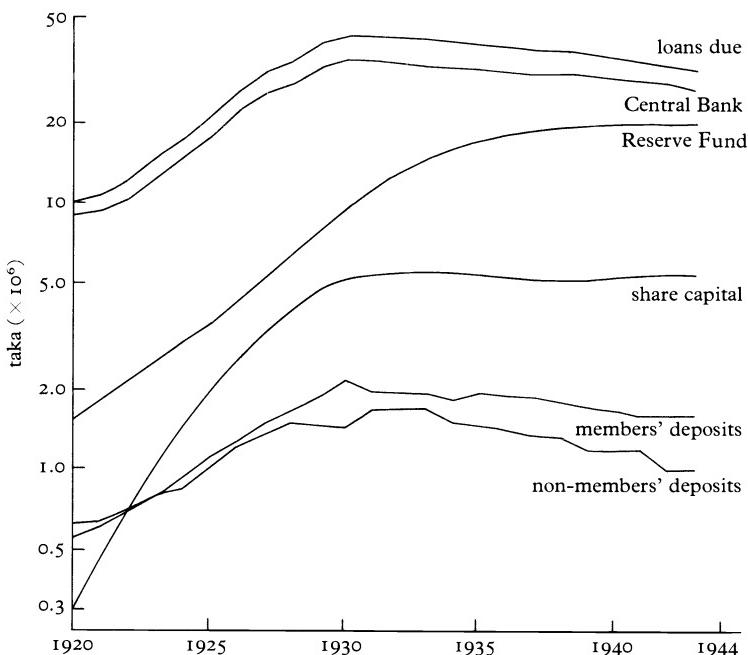

FIGURE 6.2 *Data on primary societies (all-Bengal) (log scale).*

6.12 BORROWED CAPITAL

The four sources of borrowed capital were the loans and deposits from the Government, other Societies, non-members and the Central Banks. As the contribution from the first two sources was very insignificant only the funds from the last two sources have been treated as borrowed capital. It may, however, be mentioned here that, while Central Banks contributed as much as 60.8 per cent of the total working capital, deposits from non-members accounted for only 3.1 per cent.

The annual rate of expansion once again fell short of the expansion of membership (Table 6.11). It was only in Presidency Division that the rates were more or less the same. Conversely, the disparity was most marked in Rajshahi. The quinquennial trends have the same features as for owned capital with the exception that borrowed capital per member started improving at the outset of the period. Moreover, the rates of increase were also higher. The sharp drop in the last quinquennium makes it clear that the

|------------|-------------------|---------------|---------------|---------------|---------------|--------------|
| All-Bengal | 4.7 | 102 (75.8) | 121 (72.3) | 129 (63.1) | 120 (55.7) | 63 (47.4) |
| Presidency | 5.6 | 102 | 140 | 158 | 153 | 91 |
| Burdwan | 5.6 | 119 | 166 | 170 | 148 | 106 |
| Rajshahi | 2.6 | 96 | 101 | 102 | 93 | 46 |
| Dacca | 5.3 | 104 | 128 | 144 | 134 | 70 |
| Chittagong | 5.1 | 107 | 127 | 123 | 117 | 62 |

financial assistance from the Government was far from being sufficient to keep pace with the expansion of membership.

From the preceding discussion it is clear that the Co-operative Movement in Bengal, as in other parts of India,¹ failed in its purpose of providing an effective alternative to the traditional sources of finance. At the end of four decades the Primary Societies could cover only one tenth of the agricultural borrowers, but the total credit needs of even this limited section remained unfulfilled. Of still greater significance, the Primary Societies mainly depended on borrowed capital and the proportion of overdue loans increased to such an extent that in the 1940s this accounted for more than two thirds of the total working capital. Thus, there remained a big gap between the high hopes and the actual performance of the Co-operative Movement in Bengal.

6.13 REVIEW OF OPINIONS ON THE LIMITED SUCCESS OF THE CO-OPERATIVES

Despite this record the importance of Co-operative institutions as an agency for the improvement of the socio-economic life of the rural people has been attracting increasing attention in the past two decades.² Therefore, it is important that an attempt should be made to isolate the main problems facing the Co-operative Societies in Bengal during the period under review. To

¹ T. Ghose and H. Sinha, 'Agricultural Co-operation in Bengal and the Rest of India', *Sankhya: The Indian Journal of Statistics*, Vol. 7, Part 2 (1945/46), pp. 189–203. See also *Credit Survey*, Vol. II, p. 167.

² The *Credit Survey* argues: 'co-operation has failed, but co-operation must succeed', Vol. II, p. 372.

begin with, some of the arguments put forward from time to time by various committees of enquiry, individual authors and persons directly connected with the Credit Movement may be briefly reviewed. Usually these relate to (a) the size of the Primary Societies, (b) the nature of liability, (c) the purpose of the Societies and (d) the lack of education and training in Co-operative Principles.

As to the size of the Primary Societies, as early as 1915 the Committee on Co-operation recommended that 'It is a good general rule that there should be one Society to one village and one village to one Society.'¹ It was subsequently argued that this 'was one of the reasons why the Co-operative Movement has not made any great progress in this country'.² It is arguably true that larger Societies would have had a larger membership, but it is difficult to see how this would have at all remedied the internal weaknesses discussed above. Moreover, when it is argued that organisers at the village level did not have sufficient knowledge of banking and supervision, it does not follow that larger Societies would have been more efficiently managed. In this respect the experience of the depression years when many Societies with larger membership had to be liquidated is particularly significant.

Another aspect of the Co-operative Movement which received considerable attention and was even held responsible for its failure, was the question of the nature of the liability of the Primary Societies. Thus, according to the Co-operative Planning Committee 'in most Provinces unlimited liability has not been very helpful to the progress of co-operative credit. Responsible people were kept out of the Movement by it and also it was largely illusory as there was no bar on the alienation of property by members'.³ It is true that in providing for unlimited liability for the Primary Societies too much emphasis was laid on the moral aspect of the Movement as against its business side. Thus, it was easy to argue that the 'Movement is essentially a moral one and it is individualistic rather than socialistic. It provides as a substitute for material assets honesty and moral obligations and keeps in view the moral rather than the material sanctions',⁴ but clearly such a sentiment did not take account of the socioeconomic realities of the rural life. From this, however, it does not necessarily follow that the principle of limited liability

¹ *Report of the Committee on Co-operation in India* (Calcutta, 1915), p. 16. Henceforth referred to as *Maclagan Committee*.

² Observation of a Co-operator from Utter Pradesh at the Fifteenth Conference of the Registrars of Co-operative Societies, 1947, cited by *Credit Survey*, Vol. II, p. 247.

³ Government of India, *Report of the Co-operative Planning Committee* (Bombay, 1946), pp. 22–3. See also Qureshi, *op. cit.*, p. 96. He argued that the principle of unlimited liability meant a 'romantic' approach, p. 160.

⁴ *Maclagan Committee*, p. x.

would have meant much difference to the picture of the Credit Movement which emerges in this study. This is clearly indicated by the fact that deposits from non-members accounted for only 2 per cent of the total working capital of the Primary Societies.

In this connection it is interesting that the advocates of limited liability who claimed to emphasise the 'business aspect' of the Credit Movement as against its 'romantic' aspect did not concern themselves with the legal situation regarding money lending. Before 1933 the main legislation regarding money lending was the Usurious Loan Act of 1918. Under this Act, where the rates of interest were excessive and the transaction substantially unfair the courts were empowered to reopen the transaction and relieve the debtors in respect of excessive interest. But in the absence of any statutory limits and various other defects this Act remained virtually a dead letter.¹ These limits were fixed by the Bengal Money-lenders Act of 1933, but it is interesting that these rates were higher than those on the deposits in the Credit Societies.² It was as late as 1940 when another Money-Lenders Act was passed that the statutory rates were fixed at about the same level.³ From the evidence referred to later it is clear that this legislation also failed in its purpose of regulating the rates of interest. What is important at this stage is that the advocates of the supposed effectiveness of limited liability were also being partly 'romantic' in their approach.

The third question discussed at various levels was whether the Primary Societies should be single-purpose or multi-purpose. Thus, it was pointed out by one author that one of the main weaknesses of the Societies was that credit was not linked with marketing.⁴ The idea was further extended by Nanavati to include the whole problem of rural rehabilitation by emphasising the ideal of 'Better Farming, Better Business and Better Living'.⁵ It is true that as an ideal solution to the manifold problems of rural life multi-purpose societies are much better, though it has to be kept in mind that many of the more important aspects of rural rehabilitation by their nature were outside the limits of the resources of the Primary Societies. But again this does not fully explain why the Credit Societies made such poor progress. In this respect it is significant that the condition of the limited number of multi-

¹ *Banking Enquiry Committee*, pp. 165–7.

² The prescribed rates were 15 per cent in the case of secured and 25 per cent in the case of unsecured loans as against 7 per cent to 11 per cent paid by the Credit Societies.

³ Respectively 8 per cent and 10 per cent for secured and unsecured loans.

⁴ Qureshi, *op. cit.*, p. 63.

⁵ See M. B. Nanavati, 'Re-organisation of the Co-operative Movement', *Indian Journal of Agricultural Economics* (August, 1952), pp. 33–4. See also Reserve Bank of India, Agricultural Credit Department, *Bulletin No. 2 – Co-operative Village Banks* (Bombay, 1937), pp. 29–30.

purpose societies was hardly different from that of the single-purpose societies.

The Royal Commission on Agriculture laid considerable emphasis on the lack of education and the inadequacy of the training in co-operative principles.¹ It has to be admitted that in certain respects these were important constraints on the progress of the Credit Movement. Formation of a Credit Society in a village required that at least some of the villagers had to be literate — a condition which it was difficult to fulfil when the rate of literacy was so low. But this does not explain why deposits from members constituted such as insignificant part of the working capital or why the proportion of overdue loans was so large.

Thus; these views do not fully explain, even if they are taken together, why the expectations of the Co-operative Movement were not fulfilled. The more fundamental causes lie elsewhere — mainly in the socioeconomic life of the rural areas and the inadequate realisation of the limited role which the provision for co-operative credit could play in such an environment when this was not conceived of as an integral part of an all-embracing plan for general reconstruction. Considered in this light it would seem that almost all the factors referred to above may at best be said to have played only a secondary role.²

Firstly, it may be explained why the Credit Movement made such poor progress in terms of its coverage of the rural families. The Banking Enquiry Committee argued that people in general had a preference for the loans available from money lenders.³ There is considerable element of truth in this opinion. Loans received from money lenders were more flexible in their use and more readily available than those from the Credit Societies. It may further be argued that the consequent reliance on money lenders was strengthened by the fact that often they combined in themselves the role of landlord, merchant and village headman. It is conceivable that this factor in itself would have created an obstacle in the way of curtailing the power of money lenders even if outside finances were available at the required level and required time.

But it is interesting that the Committee did not see any difficulty from the supply side, i.e. from the opposition or at least the non-co-operation of

¹ *Report of the Royal Commission on Agriculture* (London, 1928), pp. 449–50. See also *Banking Enquiry*, *op. cit.*, p. 150.

² The *Credit Survey* goes a step further and argues that the functional and structural weaknesses of the Primary Societies and the technical and educational backwardness of the members were subsidiary forms of symptom rather than the main disease itself, Vol. II, p. 253.

³ *Banking Enquiry Committee*, pp. 150–1.

the money lenders. Since they had a monopoly in the rural areas it was futile to expect that they would make their business less attractive by associating themselves with the Co-operative Movement and much less to take the initiative in the formation of Primary Societies. The money lenders were in a better position to safeguard their business when they were the only literate men in the village. In 1951 it was found that in 88 per cent of cases the money lenders were charging interest at rates higher than those stipulated by the protective legislation.¹ The ineffectiveness of legislation clearly indicates the futility of the expectation that the money lenders would, in general, voluntarily join the Co-operative Movement.

Another important factor which has to be taken into consideration in connection with the external coverage of the Credit Movement is the level of per capita income in the agricultural sector. The ideal of self-help basic to the success of the Co-operative Movement presupposes that the prospective members should have a surplus over their annual requirements. But given the low level of per capita income, and that the underlying trend was perhaps one of decline, it is clear that the larger section of the agricultural community did not have such a surplus. It would, thus, seem that poverty itself was a basic cause of why the coverage of the Credit Movement was so inadequate.² The possibility that in many cases the share capital ‘paid up’ by the members of the Primary Societies and ‘paid up’ by the latter to the Central Banks was actually the amount deducted from the loans to be advanced clearly indicates the importance of the point under discussion. Thus the overall position seems to have been such that the well-to-do section of the rural population did not join the movement in order to keep its business attractive and the general cultivators were not sufficiently enthusiastic because they did not have enough resources.

If this analysis of the socioeconomic life of the rural areas is accepted it is clear that this also largely explains why the owned capital of the Primary Societies constituted much the smaller part of their total working capital. For it follows that in areas where the Credit Societies were formed they mostly attracted prospective borrowers. The obvious result of this inadequacy

¹ *Credit Survey*, vol. 1, part 2, p. 693. These findings vindicate the opinion of the *Central Banking Enquiry Committee* (*op. cit.*, p. 433) that ‘In the present state of India he [money lender] is a necessity and, that being so, his calling will not be abolished by making it illegal.’ The argument about the opposition or non-co-operation of the money lenders is not meant to apply to all money lenders. Since we have defined the term ‘money lenders’ to include all those who lent money in the rural areas, even occasionally, there is a strong possibility that many of these lesser money lenders joined the rural societies. There is also the possibility that some of the other money lenders joined the Primary Societies mainly to take an undue share of the available funds.

² Calvert, ‘Prevailing Types of Rural Credit Societies’ in *Indian Co-operative Studies*, p. 43, cited by Hough, *op. cit.*, p. 70.

of the internal resources of the Primary Societies was the dependence on borrowed funds, mainly from the Central Banks. But since the capital available from the latter was not sufficient to meet all the credit needs of the members they must have at the same time depended on the money lenders. It is likely that such a situation further added to the reluctance of the money lenders to join the Credit Societies.

Lastly, the question of overdue loans may be taken up. Why did the proportion of overdue loans account for nine tenths of the outstanding loans at the end of the whole period? From the available evidence it seems that this was mainly due to the type of objectives for which loans were made. The Co-operative Societies Act of 1904 was silent as regards the purpose for which loans could be advanced by the Primary Societies. It was open to the Provincial Governments to make the necessary rules. When the Bill was drafted the Government of India refused to accept a proposal that loans should be granted only for productive purposes. It was argued that it would be difficult to enforce such a provision. Moreover, in the Indian circumstances it would be unwise to confine loans to productive uses only—if the raiyats must borrow for other than productive purposes they should obtain the loans from the Credit Societies rather than from the money lenders. The Co-operatives took full advantage of this latitude in the law and it seems that 50 per cent of the loans were advanced for such long-term purposes as the repayment of old debts and the purchase of land.¹ Admittedly this was a sound idea to enable the members to get rid of their accumulated obligations to the money lenders, but the difficulty was that though most of these finances were raised by the Central Banks on a short-term basis the period within which to repay the loans was not accordingly fixed. It is not known whether loans so obtained were really used for the repayment of old debts or if these became an additional burden on the members. If, however, it is assumed that the borrowers did repay at least a part of their debts it is clear that all the overdue loans in the 1920s were not, properly speaking, overdues as such.

Obviously it should not be concluded that these procedural changes would have materially improved the repayment capacity of the borrowers. As pointed out by the Reserve Bank, where debt is a chronic feature of the cultivators' life 'it can only mean a perpetual disequilibrium between his income and expenditure. The disease thus is the deficit budget and if the symptom—debt—is to be removed, the causes of the deficit budget must be treated first'.² But since the Credit Movement was not conceived of as part of a co-

¹ The purposes for which loans were advanced by the Primary Societies were mentioned in the *Annual Reports* in the pre-1920 period.

² Reserve Bank of India, Agricultural Credit Department *Bulletin No. 1*, p. 12, cited by Hough, *op. cit.*, p. 38.

ordinated programme for increasing the per capita income of the cultivators the granting of loans for the repayment of old debts essentially meant the transfer of the obligation of the borrowers from the traditional money lenders to a kind of 'institutional money lenders'. Stagnation of the economy as against a background of population growth at a fast rate suggests that even short-term loans would accumulate over time. This was clearly indicated by the huge volume of agricultural indebtedness. The Primary Societies and the Central Banks went a step further in making long-term loans. It is true that the slump in agricultural prices imposed such a severe strain that it virtually paralysed the Co-operative Movement. But considered in the light of the inadequate realisation of the limited effectiveness of institutional credit in a backward economy it would seem that essentially the main contribution of the depression was greatly to accelerate a process which had already been started earlier.

The danger of advancing long-term loans was repeatedly pointed out in the Annual Reports, but the Central Banks and the Primary Societies did not pay much attention to these warnings.¹ This was made possible, to a considerable extent, by the lack of sufficient supervision by the Co-operative Department over their activities. The Maclagan Committee recommended that there should be one Auditor for every hundred Societies.² In itself this number seems to be far from sufficient, but even this minimum requirement was not fulfilled. Thus, whereas there were 40 Auditors in 1920/21 for roughly 5800 Primary Societies in 1942/43 there were 290 Auditors for 36,100 Societies. This was so in spite of the fact that the Primary Societies were regularly paying Audit fees to the Provincial Government and by 1935 there was a surplus of 10.4 lakhs.³ Adequate supervision and direction was of considerable importance at the early stages of the Co-operative Movement, but this does not seem to have been realised.

It was pointed out that two of the reasons for the failure of the Co-operative Movement were that (a) the major part of the funds were taken by those who were in charge of the management of the Primary Societies⁴ and that (b) these members were reluctant to repay their loans.⁵ In the light of

¹ Thus, it was pointed out in the *Annual Report* of 1923/24 that until the difference between long- and short-term loans was realised 'the Central Banks and village Societies would move blindfold without looking under the surface and trying to discover what actually is being done with co-operative money'. p. 9.

² *Maclagan Committee*, p. 58.

³ This question was raised in the Provincial Legislative Council by one member who alleged that the Government was 'misappropriating' the money. See *Proceedings of the Bengal Legislative Council*, Vol. xxviii, No. 3 (1928), p. 473.

⁵ *Ibid.* See also *Central Banking Enquiry*, *op. cit.*, p. 449.

the available evidence it is difficult to question the validity of the first charge.¹ Nor is it difficult to appreciate such a phenomenon as the unequal distribution of loans if we keep in mind the fact that the available funds were too inadequate to meet all the credit requirements of the members and that rural life is characterised by marked differences in the socioeconomic influence of the different classes of households. The fact that this latter aspect of the problem was not adequately recognised once again underlines that some of the basic assumptions behind the Co-operative Movement were unrealistic. As to the second charge it is very likely that some of the members were deliberately holding up the repayment of their overdue loans, though this is not always clear from the findings of the Co-operative Department as reported in the Annual Reports in the late 1930s. But it seems that in analysing the causes of the failure of the Credit Movement an exaggerated view was often taken about the impact of the role of influential members of the Primary Societies. Speaking from the point of view of agricultural development there was perhaps nothing wrong in the unequal distribution of loans. But as elaborated later, the problem was essentially due to the fact that provision for credit was not conceived of as part of a general plan for economic development. The role of a section of the members did aggravate this basic weakness of the Credit Movement.

Thus, from the side of the coverage of the rural families and the fulfilment of their credit needs the problem was essentially either to (a) incorporate the money lenders in the Primary Societies and to ensure that they could not misuse their powers² or (b) to eliminate them by effective competition.³ With regard to the first point the efforts were far too insignificant – in one respect even contradictory – to be effective in inducing the traditional sources to surrender their profitable business. The alternative solution involved the flow of finance from outside sources. The establishment of Central Banks under the Co-operative Societies Act of 1912 was a sound decision in this direction, but as a federation of the Primary Societies lower down, these, in their turn, showed the same financial weakness. The Reserve Bank which was established in 1935 insisted that till the problem of rural indebtedness was solved and the cultivators were made credit-worthy it could not make any substantial financial accommodation.⁴ Nor could the Co-operatives look up to the Government for much more than supervision, administration and

advice. It was mainly during the last five years that some assistance was given, but this was hardly sufficient.

The problem was not, however, only to make provision for cheap credit, but also to emphasise its productive use. The evils of finance drawn from traditional sources were due partly to the high rates of interest and partly to the fact that it was not generally used to augment the per capita income of the borrowers, but to balance their deficit budgets.¹ Therefore, if the problem of rural indebtedness was to be solved what was needed was to emphasise the dynamic role of credit as against its static role – i.e. to use capital to promote a cumulative increase in per capita income. This required the integration of credit with assistance in applying new techniques, better farm management, adequate demand for increased production and facilities for marketing. In other words the overall problem was one of creating a climate for economic development.² Such an environment would have solved the problem of rural indebtedness and reduced the rate of interest by increasing the proportion of loanable funds and helping the cultivators to build up their security. In other words the forces which made credit a burden and so expensive in terms of its price would have been effectively challenged. But it would seem that the importance of such a dynamic role was not adequately realised either at the time of the inauguration of the Co-operative Movement or in the subsequent years.³

By 1944 the Debt Conciliation Boards established under the Agricultural Debtors Act of 1935 had reduced 50.0 crores of rural indebtedness to 18.00 crores.⁴ But despite these efforts and the fact that money lending was statutorily regulated total agricultural indebtedness in 1945 was estimated at 150.0 crores⁵ as against 100.0 crores in 1928/29.⁶ It is difficult to deter-

¹ One of the explanations often put forward for rural indebtedness was that the cultivators were extravagant. This explanation was not accepted by the *Deccan Riots Commission* (Para. 54 of the Report, cited by B. B. Chaudhuri, *op. cit.*, p. 338) and *Banking Enquiry Committee*, pp. 71-2.

² Such a role of credit is emphasised by the publication of the Food and Agricultural Organisation referred to earlier. See also, by the same organisation, *Agricultural Credit Through Co-operatives and Other Institutions* (Rome, 1965).

³ Thus, for example, the *Banking Enquiry Committee* (*op. cit.*, p. 450) believed that 'The only remedy for these unsatisfactory conditions which appears to offer any prospect of success is the patient and persistent education in the principles and meaning of co-operation of the members of Primary Societies by teachers competent to perform the task efficiently under adequate supervision.' Again the *Report Submitted to the Government of India* (*op. cit.*) made some recommendations for the liquidation of the existing debt of the cultivators, but as to the prevention of the accumulation of debt it contended that education would seem to be the only real and lasting corrective (pp. 14-16).

Agricultural credit

mine how far this really represents (in money terms) an increase in the total amount of indebtedness, as the two estimates are not comparable as regards coverage of the different classes of rural families. Secondly, the basis on which the estimate of 1929 was made is of doubtful validity. However, it may be safely concluded that the problem of agricultural indebtedness was far from being solved and the prominence of the money lenders as a source of agricultural credit was still unchallenged.

BENGAL LANDLORDS AND AGRICULTURE

One argument that featured prominently in the discussion leading to the introduction of the Permanent Settlement in Bengal was that such an institutional arrangement would act as a radical incentive to agricultural development. Since the zamindars would have proprietary rights to the land and the demands of the government on them would not increase, the landlords would, it was believed, in their own interest invest their profits in land. Thus, Cornwallis asserted, 'Land property will acquire a value hitherto unknown in Hindustan and the large capital possessed by many of the natives in Calcutta which are now employed in usury or monopolising salt and other necessities of life will be appropriated to the more useful purposes of purchasing and improving land'.¹ There were critics of this plan even at the time of its introduction and the experience of the subsequent years, when the failure of the expectations of Cornwallis became more and more clear, added both to the number of critics as well as to the severity of their denunciation. The Government of India believed that the desired effectiveness of the permanent settlement was not 'supported by the experience of any civilised country' and that under this system the 'cultivator was rack-rented, impoverished and oppressed'.² Again, according to the Land Revenue Commission the 'Permanent Settlement imposed on the province an iron-framework which has had the impact of stifling the enterprise and initiative of all classes of people'.³ It has been generally held that the Bengal 'monied class' invested their capital in buying or taking leases on land from the old landed class and that this practice assumed such proportions as to dry up capital for commercial or industrial enterprise.⁴ Thus, to some extent the process was the same as

¹ Cited by R. Guha, *A Rule of Property for Bengal: An Essay in the Idea of Permanent Settlement* (Paris, 1963), p. 172.

expected by Cornwallis in Bengal and experienced in England. But, in spite of this over-capitalisation, agricultural productivity in Bengal remained one of the lowest in the world.

The present chapter is an attempt to investigate why the expected capitalistic development did not take place in Bengal. Was it due to their inherently 'negative attitude' that the landlords preferred to live as social parasites? Or could it be argued that the objective economic conditions in Bengal were not favourable for the development of capitalism in agriculture? At the outset it may be mentioned that at the present stage of our knowledge about the economic history of Bengal it will be extremely difficult to offer any definite answers to these questions. In any case, the problem is too complex to be satisfactorily dealt with in one chapter. Therefore, our purpose will be only to suggest some possible lines of investigation. However, we are not concerned only with the zamindars, but the whole body of landlords which, according to the tenancy laws, included, as well as the zamindars, tenure-holders of all grades. If the land possessed by a raiyat was 33 acres or more, he was presumed to be a tenure-holder and, therefore, a landlord.

Our investigation proceeds on two assumptions usually made about the zamindari system in Bengal. Firstly, the business class invested their capital in buying up or taking leases on land. Secondly, the landlords did not take the desired initiative in agricultural development. It is likely that the transfer of commercial capital was not as marked as has been generally assumed. It is also likely that there were many landlords who did play some role in augmenting agricultural production. But in spite of these possibilities we are proceeding on the basis of these two assumptions, because sufficient evidence has not yet been presented to question their validity.¹

To begin with, let us raise two questions: (a) What role was played by English landlords in bringing about the Agricultural Revolution in England? (b) What stimulated them to play such a role? In England, where a landlord-tenant relationship existed in agriculture the landlords did take initiative in agricultural development. It is therefore useful to examine the nature of and the causal factors behind the economic role of the English landlords.

On the first question the traditional view is that the landlords played the key role in bringing about the transformation of English agriculture. They

Rai Sitanath Ray Bahadur in *Minutes of Evidence taken before the Indian Industrial Commission, 1916–18*, Vol. 2 (UK Parliamentary Papers, 1919, XVIII).

¹ The possibility that the transfer of commercial capital was not all that considerable is suggested by the findings of Dr M. S. Islam. For details see his, *The Permanent Settlement and the Landed Interests in Bengal* (Unpublished PhD thesis, University of London, 1972), Ch. 4; see also B. B. Chaudhuri, 'Land Markets in Eastern India, 1793–1940. Part II: The Changing Composition of Landed Society', *The Indian Economic and Social History Review*, Vol. XII, No. 2.

experimented with new methods on their own farms, supported agricultural societies and thus helped the wide use of the new technology in English agriculture. As to the representativeness of such landlords the students of English agricultural history are now less confident than they were in the past.¹ However, it is not denied that there were many landlords who made use of new technology in their farms. Secondly it is generally agreed that in at least one respect the English landlords did make a decisive contribution. This was in making provision for permanent capital – enclosure, drainage and farm buildings. Of these the most important was the enclosure of scattered fields into compact production units. This affected so many complicated property rights that it could not perhaps have been carried through without the compulsion exercised by the landlords. Provision for permanent capital, together with the recognition of the fixity of tenure and the practice of some landlords to share the tenants' losses in bad years, provided enterprising tenants with a favourable physical and psychological environment for making innovations in agriculture.

With regard to the second question it has to be emphasised that the interest of the landlords in making provision for permanent capital or introducing new technology in their own farms was financial return rather than agricultural development. Firstly, as the growth of population and increasing urbanisation as a result of the Industrial Revolution pushed up the price of agricultural produce, the rate of return on investment in agriculture increased. It has been estimated that the landlords' gross return on their investment was between 15 to 20 per cent as against a return of only 5 or 6 per cent from land purchase or investment in 'funds'. Thus, enclosure became by far the most profitable use of capital in connection with land and this explains the great popularity of the enclosure movement in the late eighteenth and nineteenth centuries.² Secondly, it is believed that without the requisite investment in land it was difficult for landlords to attract the substantial capitalist tenants.³ This pressure from the side of the tenants underlines the importance of the absorption of an increasing volume of manpower in the industrial sector in inducing the landlords to invest in land improvement. Thus, on the whole, it seems that it was the Industrial Revolution which,

¹ H. J. Habakkuk, 'Economic Function of the English Landlords in the Eighteenth Century', in W. E. Minchinton (ed.), *Essays in Agrarian History* (London, 1968), Vol. 1; G. E. Mingay, *English Landed Society in the Eighteenth Century* (London, 1963). For the traditional view about the role of the English landlords see, for example, Paul Mantoux, *The Industrial Revolution in the Eighteenth Century* (London, 1964), pp. 163–5.

³ Habakkuk, *op. cit.*, p. 199.

through its impact on the product market and the labour market, created favourable conditions for the land-lords to make productive investment in agriculture.¹

Now let us return to our original question as to why the Bengal landlords failed to imitate their English counterparts. The basic question is whether there was a sufficient inducement for the Bengal landlords to invest for agricultural development. The fundamental requirement from the angle of capitalistic development is that the potential investor must believe that investment will be more profitable to him than consumption. Secondly, the opportunity cost must not be higher than the rate of return.

In the agricultural sector capital may be invested for the extension of cultivation to new areas and/or to increase the productive power of the land already under cultivation. Such (productive) investment does not only increase the income of the capitalist farmer, but it also leads to an expansion of agricultural output. Secondly, capital may be invested only for purchasing the proprietary rights in land or for money lending or trade in agricultural produce (unproductive investment). In such a case there is only a distributive effect.² From the above account, capital will be invested for productive or unproductive purposes depending on the relative rate of estimated return. The Industrial Revolution in England created a favourable environment for productive investment in agriculture and landlords took advantage of the opportunities. Were the objective economic conditions in Bengal so favourable for productive investment?

Two main features characterised the changes which took place in the economic life of Bengal after the establishment of foreign rule. Firstly, in spite of the rapid growth of population under more stable conditions, the size of the domestic market for agricultural production remained limited. As the rate of industrialisation remained insignificant, Bengal's economy continued to be characterised by its heavy dependence on agriculture. Thus, whereas in England rapid progress in industrialisation was pushing up the demand for agricultural produce, under the particular conditions of Bengal growth of population was increasing the pressure on the available land for cultivation.³ In England the percentage of the population in agriculture declined from about 60–80 per cent at the end of the seventeenth century to 36 per

¹ As mentioned in Chapter one this is not, however, to suggest that the basic relationship between agriculture and industry was one of unidirectional causation.

² Leibenstein calls the first type of investment 'zero-sum enterprise' and the second type 'positive-sum enterprise'. For details, see H. Leibenstein, *Economic Backwardness and Economic Growth* (New York, 1957), pp. 112–119.

³ If we believe that in the eighteenth and nineteenth centuries the foreign rulers followed a policy of 'deindustrialisation' or 'ruralisation', this would mean that the pressure of population on land did not increase only in absolute terms, but also in relative terms.

cent at the beginning of the nineteenth and 7 per cent in 1921.¹ On the other hand, the percentage of total population dependent on agriculture in Bengal was as high as 77.3 per cent in 1921.² Once again, whereas the average size of a holding was 111 acres in England,³ it was only six acres in Bengal.⁴ In these circumstances, it is clear that the level of rent in Bengal was going to be 'determined not by the fertility of land, but by the fertility of human beings'.⁵ Thus, as land was the scarce factor of production it would have commanded a high price in terms of rent under any system of land tenure. But the institutional monopoly granted to the landlords in 1793 would seem to have given them a better opportunity to take advantage of the scramble for land.

Secondly, the scheme of economic development based on international specialisation pursued by the foreign rulers under the policy of selective intervention led to an expansion of the foreign demand for agricultural produce. The improvement of the means of transport and communication, the increase of both the volume and value of export and the development of certain industrial and commercial centres within the country made the agricultural sector of Bengal more market-oriented than in the past. To this extent the establishment of foreign rule must be said to have created conditions for productive investment in agriculture. At the time of the introduction of permanent settlement vast areas of Bengal were yet to be brought under cultivation⁶ and the revenue-demand of the government on the landlords was fixed. It may be argued that under such circumstances the Bengal landlords, like many of their counterparts in England, could have invested capital in large-scale farming.

Thus, to summarise this part of the discussion, it would seem that the establishment of foreign rule created conditions both for productive and non-productive investment in Bengal agriculture. But it is clear that the Bengal landlords preferred the latter type of investment; they invested their capital for the purchase of proprietary rights in land without trying to improve its

³ This was the estimated average in England and Wales in 1851. The position at the turn of the nineteenth century is not believed to have been much different. For details see, J. H. Clapham, *An Economic History of Modern Britain* (Cambridge, 1932), pp. 264, 451.

⁴ *LRC*, p. 84.

⁵ D. Warriner, 'Land Reform and Economic Development', in C. K. Eicher and L. W. Witt (eds.), *Agriculture and Economic Development* (New York, 1964), pp. 272–98.

⁶ It has been estimated that 1/3 to 2/3 of the total area in Bengal was cultivable waste. See, *LRC*, Vol. II, p. 211.

productive quality. As a tentative generalisation it may be suggested that this tendency of the landlords was due to the fact that the expected rate of return on non-productive investment appeared to be higher than that on the productive investment. This assumption is based upon the following considerations.

Returns on capital invested in agricultural production tend to materialise slowly. This, together with the fact that there are usually large fluctuations in the price level and yield per acre, discourages large-scale investment even when production is meant for the domestic market. It is natural that such a tendency would be stronger when the production was oriented towards meeting the demands of the foreign buyers. Firstly there are the difficulties of foreseeing accurately such factors as the nature of current demand in the world market and the prices to be obtained in competition with other countries. Secondly, the export trade in agricultural produce was monopolised by foreigners. This may have had the effect of depressing the share of domestic producers in the benefits which would have otherwise accrued to them from the expansion of foreign demand. Such risk and uncertainties would seem to have had the effect of making the rate of return on the socially productive investment of capital appear lower.

Thus, the Bengal landlords' preference for non-productive investment would seem to have been due to the fact that their monopoly control of land enabled them, under conditions of the adverse land-man ratio, to gain a rate of return higher than that on productive investment in agriculture. The preference of the landlords in making investment in land purchase, money lending and trade in agricultural produce to those fields which would have led to a net gain in agricultural output may appear irrational or traditional. But, as pointed out by Aubrey, this kind of thinking implies a welfare judgement which does not conform to the profit-oriented investment criterion of the investing individual.¹

It is true that the landlords did not always enjoy unrestricted control over land. Beginning from the Tenancy Act of 1859 the area held by the occupancy raiyats increased as the number of cultivators belonging to this class increased and the freedom of the landlords to let land at whatever rate they could charge was curtailed in respect of these tenants. Such interference with the rental market represented a significant shift from the policy of *laissez-faire* implicit in the plan of 1793. But the landlords were still left with considerable power to increase the rate of rent without taking initiative in

¹ H. G. Aubrey, 'Investment Decisions in Underdeveloped Countries', in National Bureau of Economic Research, *Capital Formation and Economic Growth* (Princeton, 1955).

agricultural development. Thus, under the Tenancy Acts the money-rent payable by the occupancy raiyats could be increased on the following grounds:

- (a) the rate was below the prevailing rate in the village or neighbouring village,
- (b) rise in the average price of food crops,
- (c) improvement of the productive quality of land by the action of the landlords,
- (d) improvement effected by fluvial action.

Moreover, the landlords were entitled to a fee of 20 per cent of the value of land transferred or leasehold created by a raiyat.¹ Thus, the tenancy laws left sufficient scope for the landlords to increase the rate of rent payable by raiyats. It may be safely assumed that, under conditions of growing pressure of population on land, the landlords took the advantage to increase rent per unit of land.

It is difficult to estimate the extent to which rent per acre of land increased in the nineteenth century. Gross rental of the landlords estimated on the basis of Road Cess was published by the government beginning from 1871. But it was not shown to what extent the increase in the gross rental was due to (a) the extension of cultivation to new areas and (b) enhancement of the rate of rent per acre. However, some idea may be made from the figures relating to the period after the first decade of the present century when the extension of cultivation seems to have come to a virtual end (Table 7.1).

It seems that during the quarter century following 1914 the rent paid by the raiyats increased by nearly 40 per cent. It should be noted that in 1936/37 five per cent of the legal rental was paid by the raiyats with fixed rent and some lands were held by rent-free raiyats. Secondly, this increase in the

TABLE 7.1 *Gross rental (in thousand Rs)*

rate of rent does not show the increase in the collection of illegal cesses which is likely to have taken place during the same period.¹ Thirdly, these figures on gross rental do not include the income from the transfer fee paid by the raiyats. It is possible that the income from this source increased in view of the increased transfer of land. Fourthly, though population increased at a high rate during this period total agricultural production remained more or less stagnant. However, it is quite clear that the landlords were making substantial gains from their monopoly control of land. The opportunity of making profit from the proprietary rights in land was hardly conducive to the productive investment of capital by the landlords.

Market conditions in Japan were far more favourable than in Bengal, but even then the concentration of land in the hands of the landlords did not lead to large-scale farming by them. This was mainly due to the high rent which characterised Japanese agriculture after 1873. So long as the landlords could sit back and collect 50 to 60 per cent of the produce as rent, there was little incentive for them to become capitalist farmers.² From the available statistics it does not seem that the rate of rent collected by the Bengal landlords from the raiyats was as high as in Japan. But in the light of this experience it does not seem to be difficult to explain why the Bengal landlords, instead of undertaking large scale farming, remained satisfied only with the legal proprietorship of land (i.e. unproductive investment of capital).³

It may, however, be argued that the landlords could have helped agricultural development by undertaking such measures as the dissemination of the use of fertiliser, manures, improved seeds and breeds among the cultivators. Capital requirements for such intensive farming methods are usually modest and this takes mainly the form of working capital which yields a quick return by way of increased output. If the landlords had invested their capital for such purpose, they could have increased the rate of rent per acre of land. The usual explanation which has been given for the lack of initiative in this direction was the existence of different grades of subinfeudation.

¹ Illegal cess was estimated by some members of the Provincial Legislative Council as ranging between 60 and 120 million rupees. Cited by R. K. Mukherjee, *Dynamics of a Rural Society: A Study of the Economic Structure in Bengal Villages* (Berlin, 1957).

² Nobutaka Ike, 'Taxation and Land-ownership in the Westernisation of Japan', *The Journal of Economic History*, Vol. VII, No. 1 (1947).

³ The Royal Commission on Agriculture felt that one of the greatest drawbacks in the way of agricultural development in India was the absence of large farms. (See Report, p. 425). But considered in the context of the problems discussed here it would seem that the absence of large farms was not the cause, but the result of the failure of Bengal landlords to become capitalist farmers. In this study it is not being suggested that large-scale farming was a condition of success. We are only trying to explain why the Bengal landlords, unlike their English counterparts, did not start large-scale farming.

tion between the actual cultivators and the original tenure-holders or proprietors. Thus, according to the Land Revenue Commission this growth of intermediaries prevented the 'Zamindars from fulfilling the functions which provide the economic justification for a landlord and tenant system because with few exceptions the tenure-holders above the raiyots have neither the incentive nor the capital to effect agricultural improvement. The Zamindar to-day cannot obtain an enhancement of rent even for any improvement which he makes and he feels that he is no longer responsible for improvement'.¹ The Minority Report which mainly reflected the opinion of the different Landholder's Associations and the British India Association also took the same view.²

At first sight it seems that this thesis of the Land Revenue Commission offers a satisfactory explanation of the problem under investigation. But a closer scrutiny suggests that this view is somewhat superficial. Firstly, why should it be assumed that all the tenure-holders immediately above the raiyats did not have either the capital or the incentive to effect agricultural development? Is it not true that many of these landlords invested capital in money-lending business and other profitable alternatives? Under the tenancy legislation the landlords were allowed to increase the rate of rent for any improvement effected by them in the productive power of land. Moreover, from the District Settlement Reports it is clear that in most cases the rent payable by the tenure-holders to the superior landlords was fixed. Thus it is not correct to argue that these tenure-holders did not have the incentive or the capital to improve the productive power of land.

Secondly, it is true that the original landlords did not have an incentive to invest capital in the land in the case of which there were intermediaries between them and the raiyats. But the important question that has to be asked in this connection is what portion of land was affected by the creation of intermediaries? It is difficult to obtain detailed evidence on this question. However, if the situation in three districts is regarded as significant, it would appear that the Land Revenue Commission grossly exaggerated the difficulties arising out of the creation of tenure-holders. Thus, while in Dacca and Mymensingh the landlords had direct relationship with the raiyats in respect of respectively 64 and 66 per cent of the total land in their zamindari, in Faridpur it was 34 per cent.³ This evidence suggests that a sizable portion

¹ *LRC*, p. 34.

² *Ibid.*, p. 215.

³ For the evidence on Dacca see *Final Report on the Survey and Settlement Operations in the District of Dacca, 1910–1917* (Calcutta, 1917), p. 69; for Faridpur see *Final Report on the Survey and Settlement Operations in the Faridpur District, 1910–1914* (Calcutta, 1916), p. 25; for Mymensingh see, *Final Report on the Survey and Settlement Operations in the District of Mymensingh, 1908–1919* (Calcutta, 1920). Calculated from appendix 9 and 10. The following

of the zamindari land remained unaffected by the growth of intermediaries. But the superior landlords did not invest capital to improve the productive power of the land in respect of which they had direct dealings with the raiyats. Thus, it seems that the thesis of the Land Revenue Commission does not really explain why the landlords did not invest through the raiyats.

The real explanation seems to lie in the considerations mentioned earlier. With regard to the question of productive investment of capital directly by the landlords it has been argued that such investment involved so many risks and uncertainties that the rate of return appeared to be lower than the rate of return on land purchase. It is but natural that such a rate of return would appear to be lower if the landlords were going to invest capital through the agency of the tenants who were so numerous, for two reasons: with the standard of living of most of the tenants so low the landlords would have found it very difficult to raise the additional rent on improved (e.g. irrigated) land; secondly, as in many cases the landlords were sure to be involved in litigation with the tenants, the cost of collection of rent would have been high. From this it would follow that even if there were no intermediaries between the Zamindars and the cultivators, the former would have hardly taken the initiative in productive investment in agriculture.

At this stage it would be quite legitimate to ask: if monopoly control of land had created an opportunity for the landlords to claim a high price for land, why were the different grades of tenure-holders created? Secondly, if there was any need to create intermediaries, why in most cases were the rates of rent per acre paid by them fixed? Clearly such an arrangement went against the interests of the original landlords or tenure-holders. Thus, for example, it was shown in the Settlement Report on the Mymensingh district that the average rent paid by the tenure-holders of the first grade was less than 12 annas per acre. But the average rate of rent paid by the raiyats under the original landlords was just under Rs 2/12. Again, whereas the average rate of rent paid by the tenure-holders of the second grade was less than one rupee, the average rate paid by the raiyats under the first grade tenure-holders was nearly Rs 3. This meant that both the original landlords and the first-grade tenure-holders were incurring a loss of nearly Rs 2 per acre by the creation of intermediaries. It was calculated that as a result of the creation of intermediaries the superior landlords in Dacca, Faridpur, Bakerganj and Mymensingh lost respectively Rs 60, 63, 200 and 102 per 100 acres.

information is available from the Settlement Reports regarding the number of the grades of intermediaries: Dacca (9), Jessor (6 or 7), Khulna (8), Bogra (10), Bakerganj (12), and Mymensingh (3). These show that the opinion of the *Indian Statutory Commission* (cited by *Bengal Land Revenue Commission*, p. 37) that there were 35 to 50 grades of tenure holders is grossly exaggerated.

As pointed out earlier, it seems that both the number of the grades of tenure-holders and the proportion of land in which such interests were created have been exaggerated. However the fact that such interests were created contradicts our contention that the purchase of land was so profitable and/or the landlords were really aware of such profit-making possibilities. Nothing definite can be said on this score unless we know to what extent the creation of intermediaries was due to (a) the rigidity in the collection of rent by the government, particularly in the decades immediately following 1793, (b) the fact that the lands of the landlords were scattered in different districts and (c) the acceptance of other occupations by landlords which took them permanently to the urban areas. The landlords constituted the dominant class in the society. Therefore, it is but natural that many among the landlords who had taken up other occupations would like to maintain their legal rights in land and, thus, have the satisfaction of being known as a landlord.

By the time the Agricultural Revolution started in England the tradition of the landlords' engaging in large-scale farming and providing permanent capital to the tenants was well established, as this was the practice in the preceding two centuries when the entire economy was undergoing gradual changes. The contribution of the Industrial Revolution of the late eighteenth century was essentially to widen the scale of this practice by creating greater opportunities for productive investment in agriculture. Against this the economy of Bengal (as that of any other part of India) had a long history of relative stagnation during which the landlords had hardly looked upon land as an avenue of productive investment. One important factor in this respect was the fact that since they were not the owners of land, there was uncertainty about the enjoyment of the fruits of investment by the landlords. Considered against this background it seems that the declaration of the proprietary rights in land was a necessary step in transforming the traditional attitude of the landlords, but this was not a sufficient condition. Such a condition could be created in an environment in which returns on productive investment would appear to be greater than the profit from the alternative sources – monopoly control of land, money-lending and trade in agricultural produce. Economic development on the basis of international specialisation does not seem to have created such an economic environment in Bengal.

As pointed out earlier the experience of the years after 1793 when the landlords did not show the desired initiative in agricultural development seems to have had considerable influence on the policy of the foreign rulers in favour of establishing direct relationship with the peasant and the village communities.¹ In Bengal, however, the government followed a policy of com-

¹ Eric Stokes, *The English Utilitarians and India* (Oxford, 1959), Ch. II.

promise i.e. a policy of keeping intact the institutional monopoly of the landlords and at the same time giving relief to the raiyats. The protective legislation by which such an objective was sought was not, however, passed till the question of the landlord-tenant relationship had assumed political significance. Thus, as pointed out by Mr Ilbert while introducing the Rent Bill of 1885, the efforts of the landlords to obtain higher rents and the opposition of the tenant to what they considered as unjust was creating a serious state of affairs.¹ In these circumstances the government could neither restore the raiyats to their status in 1793 nor 'attack the vested interest of the landlords in any degree'.² Therefore, the protective laws which were being passed had to 'contain much that is in the nature of expedients, adjustments and compromises'.³ The result was that though the landlords were not fulfilling their economic role they were allowed to obtain, as mentioned earlier, enhancement of rent on many grounds.

This is not, however, to suggest that the landlords would not have claimed rent at an enhanced rate if there were legal sanctions against it.⁴ Similarly, it cannot be expected that the additional income earned by the government from the abolition of landlordism would have been spent in a co-ordinated plan for agricultural development. In the raiyatwary areas the government were the landlords as the recipient of economic rent, but under the prevailing doctrine of *laissez-faire* its role in agricultural development remained limited. Thus, the protective laws were quite close to the realities of economic life of British India. But such a policy of compromise could at best create conditions for the perpetuation of economic stagnation. It is interesting that even in the 1920s when the government had abandoned the policy of *laissez-faire* it sought to maintain the compromise by asking the Royal Commission on Agriculture not to make any recommendation regarding the 'existing system of land-ownership or tenancy or of assessment of revenue'.⁵

It has, however, to be mentioned that the attitude of the nationalist leaders and newspapers to the question of landlordism was not different either. In the last quarter of the nineteenth century they gave full support to the protective legislation against the powerful opposition from landlords. There were differences of opinion in matters of detail and some of the leaders even took

⁴ This is suggested by the failure of the Bombay Tenancy Act which fixed a ceiling on rental demand. Cited by G. Myrdal, *Asian Drama: An Enquiry into the Poverty of Nations* (London, 1968), Vol. II, pp. 1328-9.

⁵ Cited by R. P. Dutt, *India To-day* (Bombay, 1949), p. 182.

the side of the landlords, but the main body of opinion was that such legislation was essential for the well-being of the peasantry.¹ It is interesting that though many of these leaders demanded the reduction or fixing of revenue in other provinces as an incentive for greater productive efforts by the cultivators and as a safeguard against famines, they do not seem to have opposed either the restricted or the unrestricted rights given to the landlords to increase the rental paid respectively by the cash-paying occupancy raiyats and other categories of raiyats and under-raiyats. It is difficult to accept the prevailing view that such measures would have really offered a solution to the basic problems of the agrarian economy of these provinces. However, the fact that the nationalist leaders took such a different line in Bengal seems to bring out some of the inherent complications arising from the concentration of interest in landed property.

These complications were more sharply focused in the 1920s and 1930s. The first occasion came in 1923 when Sir John Keir proposed, in his amendment to the Tenancy Act of 1885, the extension of occupancy rights to the share croppers and other measures generally unfavourable to the landlords. This drew such strong protests from both within and outside the Bengal Legislative Council that the Bill had to be abandoned.² The Act of 1885 was at last amended in 1928, but with the support of the Congress and Swaraj members the landlords successfully resisted a move by a section of the members to deprive them of their right to collect transfer fee and pre-emption and even to giving a legal status to the share croppers. Thus, even in the 1920s the policy of the nationalist leaders remained essentially one of compromise, i.e. to grant greater security to the raiyats and at the same time to safeguard the interest of the landlords. Again, there were differences of opinion as to the extent of rights to be granted to the different grades of the raiyats, but there was as yet no proposal for a radical change in the existing system. The first serious proposal for the abolition of the zamindari system was made in 1932 at a conference of the Bengal Provincial Praja Samity formed in 1929 and later renamed as the Krishak Praja Party.³ This party contested the provincial elections of 1937 on the basis of its programme for the abolition of landlordism without compensation. The coalition ministry which was formed under the Premiership of A. K. Fazlul Huq, the leader of the Krishak Praja Party, appointed a Commission to devise ways

² See *LRC*, p. 28.

³ For details of the background of the formation of this party and the various other demands made at this conference relating to the agrarian economy, see A. M. Ahmed, *Amar Dekha Rajnitir Panchash Basar* (Dacca, 1968), Chs. iv–xii.

and means to replace the Permanent Settlement 'by a more equitable system and laws suitable to the needs and requirements of the people' as, it was argued, it had 'arrested the economic growth and development of the province and had adversely affected the national outlook of the people'.¹ The Commission recommended the abolition of landlordism with compensation, but this was not implemented.

However, the fact that there was such a move compelled the other political parties to define their policy with regard to the Permanent Settlement more categorically than they had done before. In the late 1920s the 'nationalists had reached a turning point. Their increasing sense of political power combined with the catastrophic economic events brought sharply into focus the fact that the long preparation for political education must be accompanied by a definite programme of economic policy'.² This was particularly true with regard to the Congress. The increased emphasis on the problems of rural life which the changed circumstances called for and the argument of the Krishak Praja Party that these were due to the prevailing system of landownership and should, therefore, be abolished must have created a dilemma for the Congress. For it could neither alienate the support of the landlords nor overlook the problems of the rural masses who were now empowered to vote. So, on the one hand, the party openly opposed the abolition of the Permanent Settlement³ and, on the other, championed the cause of the reconstruction of the rural economy. The policies which were formulated remained, however, vague, impractical and inadequate as a solution to the basic problems of poverty.⁴

The Muslim League also opposed the idea of the abolition of landlordism. This was in spite of the fact that the landlords mostly belonged to the Hindu community and thus offered the League leaders a great opportunity to enlist the support of the Muslim masses. It is true that subsequently this party abandoned its opposition when it entered into a coalition with the Krishak

² K. N. Chaudhuri, 'Economic Problems and Indian Independence', in C. H. Philips and M. D. Wainwright (eds.), *The Partition of India: Policies and Perspectives, 1935–47* (London, 1970), pp. 294–315. This work discusses in detail the policies of the different parties with regard to the economic problems of the time.

³ Thus, in 1931 the working committee of the Congress passed a resolution assuring the zamindars that there was no design on interests legitimately acquired and appealing to the landed and monied class for financial help. See *Indian Annual Register* (1931), Vol. II, p. 86. The dilemma faced by Congress is further shown by the evidence cited earlier that in 1926 a zamindar asked his tenants to raise Rs3000 for the payment of his contribution to the Congress. For details see, *Proceedings of the Bengal Legislative Council*, 1927, Vol. xxv, No. 2, pp. 98–9.

⁴ See, for example, the resolutions passed at Karachi in 1931. Quoted by Chaudhuri, *op. cit.*, p. 301.

Praja Party,¹ but it would seem that this change of attitude was more apparent than real.

The reaction of the landlords was predictably very strong. They had always zealously tried to safeguard all the benefits which could be obtained from their monopoly control of land. The result was that the provisions of the Tenancy Act of 1885 and its amendment in 1928 were less favourable to the tenants than they were originally intended to be.² The usual landlords' defence was that the protective legislation was a violation of the declaration of proprietary rights made in 1793. Now when they were threatened with the total abolition of their rights, they made the further claim that they were a minority community and as such were entitled to special protection by the Provincial Governor under the Act of 1935.³ Some of the more determined landlords went to the extent of declaring their support for the continuation of foreign rule.⁴

The replacement of the Permanent Settlement by the establishment of a direct relationship between the government and the cultivators was a necessary condition for the modernisation of Bengal agriculture. But clearly, in itself, this was not going to be sufficient. Such a condition could be fulfilled if the surplus extracted from the agricultural sector in the form of rent was spent by the government for experimenting with and the diffusion of new techniques of production. The fact that neither Congress nor the government recognised the necessity of abolishing landlordism made their plans for agricultural development somewhat contradictory. On the other hand, from the resolution quoted earlier it would seem that the plan of the Krishak Praja Party was not conceived in a spirit of facilitating official efforts for modernising the agricultural sector. In other words, abolition of the Permanent Settlement was identified with the solution of the manifold problems of the rural economy of Bengal.⁵ But whatever might have been the

⁴ Thus, in 1938 the Chairman of the All-India Landlords' Association declared, 'If we are to exist as a class, it is our duty to strengthen the hold of the government.' Cited by S. G. Madim, *Need for Institutional Changes and Regional Planning for Optimal Development of the Agricultural Resources of India* (Wisconsin, 1949), p. 33.

⁵ This argument that the change of tenurial arrangements does not automatically solve the problem of low productivity is clearly borne out by the experience in Bangladesh. Here superior landlordism was abolished in 1950, but till the middle of the 1960s productivity remained as low as it was before the abolition of the Permanent Settlement. The proximate economic effect of the abolition of the Permanent Settlement remained confined to an enhancement of government revenue. For details see Abu Abdullah, *Land Reform and Agrarian Change in Bangladesh* (Dacca, 1973), pp. 25–37.

motive of the Krishak Praja Party it is clear that their call to do away with landlordism pointed the way in which the tenurial system had to be changed sooner or later.

As mentioned earlier, in the present stage of our knowledge about the different aspects of landlordism in Bengal it is not possible to form a clear idea about the question why the landlords did not fulfil their economic role. But the points which have been raised in this chapter would suggest that the main problem was the absence of a sufficiently favourable economic environment to encourage private agencies such as landlords to improve agriculture, either directly through their own efforts or through their tenants. The chief factor which accounted for the absence of such a favourable environment was the very slow pace of industrialisation and the consequent restricted nature of the market and the high demand for land by the peasant producers. In these circumstances, the abolition of the zamindari system had to be the first step towards the modernisation of the agricultural sector. But such an idea was not favoured either by the foreign government or the major political parties of India, though there was increasing awareness of the problems of the rural areas. The only move which was made came in the changed circumstances of the 1930s, but it did not succeed. Evidently political and ideological evolution in India had not yet reached the stage when a drastic change in the land system could be carried out.

CONCLUSION

In this work an attempt has been made to present a quantitative picture of the performance of the agriculture of Bengal during the period from 1920/21 to 1945/46. The main emphasis has been on the trends in crop output and its two determinants – acreage under cultivation and yield. In the light of the available data from independent sources, we have seen that the officially published data on acreage were mostly underestimated and those on yield overestimated, but at least in the case of the former the pattern was not uniform over the entire period. The acreage data have accordingly been revised and it has been contended that the trends estimated from the revised series can be expected to provide a more reliable picture of the agrarian economy of Bengal. The picture which thus emerges has four important features.

During the quarter century from 1920 there was hardly any improvement in yield at the aggregate level and only a marginal expansion of the acreage under cultivation. The obvious result was that there was a marked disparity between population growth and crop production. However, there were considerable differences in the trends of the two crop groups – food crops and cash crops. Thus, in the case of the former a small expansion of acreage was accompanied by a corresponding decline in yield. This was due mainly to the stagnation of the acreage and yield of winter rice. Acreage and yield of minor crops like wheat, barley and gram increased, but their combined weight was so small that this increase could hardly improve the aggregate picture in this group of crops. The rate of expansion of the acreage under cash crops was even smaller, but the yield per acre increased considerably. The rate of improvement of the yield of jute, the largest single crop in this group, was very low, but the improvement in the case of other crops, particularly sugarcane, was very marked; overall, the yield and acreage of the major crops declined or remained more or less stagnant, and those of the minor ones increased. The example of acreage under the minor crops suggests the direction in which the expansion of acreage is likely to take place in a long settled country – through an increase in double-cropping; most of these minor crops are raised as secondary crops.

Secondly, it is significant that though the trends in the revised series

Conclusion

are more adverse than in the official series they are much better than those estimated by Blyn. This would substantiate the belief that the inclusion of Bihar and Orissa considerably depressed the trend rates for Bengal proper. It is also significant that the trends in our revised series are more in conformity with the experience in other parts of India during this period than shown either in the officially published data or by Blyn.

Thirdly, agricultural trends in the five regional units of Bengal varied considerably both with regard to area under cultivation and yield per acre. In some cases these dissimilarities seem to reflect the differences in geo-physical conditions or the change in intensity of cultivation which took place during these years.

It is not difficult to appreciate why there was virtual stagnation in the all-crop acreage since the scope for the extension of cultivation to new areas was limited. But why was there no significant improvement in yield per acre despite the relative abundance of labour? Could it be argued that this was due to the lack of efficiency on the part of the cultivators in the allocation of the factors of production? It has not been possible, for lack of data, to investigate this specific problem. Instead as an alternative test we have examined whether the cultivators were responsive to changes in the price level using data on individual crops and aggregated crops. No significant elasticity of all-crop acreage has been found with regard to changes in the terms of trade with the non-agricultural sector. But a closer look at specific considerations affecting production during a period of falling prices, and given limited scope for increasing production during a period of rising prices, does not suggest any 'perversity' or 'survival-mindedness' in the production behaviour of the cultivators. Greater insight into the 'rationality' of production decisions by the peasantry is provided by findings on the elasticity of individual crop acreage with regard to changes in relative prices and yields. For these show that, though the inelastic supply of the most important production input – land – did not allow the Bengal cultivators to increase the total acreage under cultivation, they were still maximising their proceeds from the given resources by crops that were more profitable either as a result of rise in relative price or yield. As indicated by the findings on the price elasticity of the acreage under autumn rice it is also clear that such response was not confined to cash crops. Cultivation of food crops was responsive to changes in price where there was adequate scope for substitution with alternative crops. In spite of the obvious limitations of the available data and the method of estimation it would, therefore, seem that cultivators were taking 'rational' production decisions such as were desirable within the given technological and institutional constraints.

The real explanation for the low productivity and the near-zero trend

during the period under review would thus seem to be due to the low level of capital formation. It could be argued that capital formation was adversely affected by the low and declining per capita income in the agricultural sector. It has not been possible to estimate either the trends in capital formation or its proportion in total income in the rural areas. Instead estimates have been presented on the trends of the four items of physical capital involved in Bengal agriculture – land, animal labour, occupied houses and ploughs. Land has been included as an index of the investment of money and effort in expanding productive acreage as opposed to that which may have increased or prevented the fall in the productivity of land already under cultivation. The findings substantiate our assumption that in an agricultural system characterised by relative abundance of labour supply and stagnant technology most of the increase in capital formation is likely to take a form which would expand the productive acreage. There was a considerable increase in the number of houses but it is not known if this was at the cost of changes in size and type. On the other hand the number of ploughs and animal labour declined from the beginning of the 1930s. In view of the nature of the crop statistics it is difficult to say anything definite as to whether this decline adversely affected the productivity per unit of land. But if estimated trends are considered reliable, it would seem that yield per acre was not significantly affected. This would indicate either the presence of surplus capacity at the beginning of the period or a shift towards other categories of investment. The possibility of surplus capacity during the initial years which appears to be more likely would strengthen the belief that the scope for obtaining increased output from the additional use of the traditional factors of production was limited or even negligible. It would therefore follow that the basic problem was not the inadequacy of investment in the traditional factors of production as such but the absence of technological innovations.

Closely connected with the problem of investment made by the cultivators is the availability of credit. For a long time the only source of credit in the rural areas was the money-lenders. But the finances drawn from them became a burden on the borrowers instead of contributing to their prosperity. The solution offered to the problems of high rates of interest and indebtedness by the inauguration of the Co-operative Credit Movement and the statutory regulation of money lending had two important limitations. Firstly, there was inadequate realisation of the need for making provision for credit as part of a wider plan for economic development; provision for cheap credit was not accompanied by the development and diffusion of such new inputs as would result in a sustained increase in output. Secondly, some of the underlying assumptions behind the Credit Movement and the statutory restriction on the rate of interest to be charged by the money-lenders were

Conclusion

unrealistic in that they did not take note of the specific forces which pushed up the price of credit and gave the money-lenders a hold in the rural economy. The result was that the progress of the Credit Movement remained very slow and the problem of rural indebtedness was far from being solved. Thus, even at the height of the Co-operative Movement only 10 per cent of the borrowers in the agricultural sector were covered by the Primary Societies and only 24 per cent of their credit needs were met. And most important of all, in the 1940s nine tenths of the outstanding loans were overdue. Thus, evidently there remained a wide gap between the expectations and the actual performance of the Co-operative Movement.

Finally we have raised some questions about the reasons why the expectations that the landlords would take initiatives in agricultural development were not fulfilled in spite of the flow of capital to agriculture. The discussion suggested that under the prevailing circumstances the landlords found it more profitable to take advantage of the high demand for land than to make productive investment. The greatest disincentive to making productive investment in large-scale farming was that the market for produce was uncertain and inelastic. As against this disincentive was the opportunity to demand a high rent for land. Such an environment made private agencies such as landlords unsuitable for the purpose of improving agriculture either through their direct efforts or indirectly through the peasant cultivators. Under these circumstances what was needed was the abolition of the monopoly control of land by the landlords and the use of the surplus generated in agriculture for its modernisation. But political considerations made such a move unacceptable either to the foreign government or to the major political parties of India. Instead a policy of compromise was pursued. This is noticed in the attempts to regulate the profit which the landlords made from their monopoly control of land and to grant security to increasing number of raiyats and under-raiyats. In the interests of agricultural development the government maintained an Agricultural Department and experimental centres, but since most of the surplus in agriculture was being expropriated by the landlords the official efforts remained nominal.

Thus, the government could not do much because it was financially handicapped, the landlords did not take the initiative because they did not find it profitable and the raiyats could not improve their productive techniques because they could not develop new inputs, and the inputs which were developed at the experimental centres were not available on the market.

To summarise, the picture of the agrarian economy of Bengal which thus emerges is clear enough – it had reached an equilibrium at a low level of production. This is shown by the near-constancy of cultivated area and a near-zero trend in yield per acre; this equilibrium at a low level of pro-

ductivity reflected the efficiency of the known techniques of production. The price of credit remained high as the money lenders were still virtually the only source; and the finances drawn from them, to the extent that these were used for directly productive purposes, continued to be invested in the traditional factors of production. The result was that agricultural indebtedness was still very acute. The solution to these problems would have meant action to an extent not forthcoming either from the landlords, or from the government.

APPENDIX: STATISTICAL TABLES

Appendix: statistical tables

| | | | | | |
|------|------|------|------|------|------|
| 1943 | 3637 | 1679 | 4619 | 2132 | 1034 |
| 1944 | 4564 | 1742 | 4564 | 1742 | 855 |
| 1945 | 4155 | 1620 | 3511 | 1620 | 873 |

Note: As explained in chapter 1, section 1.6 the figures in the revised series up to 1940/41 are obtained by using the same Revision Factor, i.e., the margin of error during these years is assumed to be uniform. Separate Revision Factors are used for 1941/42 to 1943/44 and 1945/46.

In the case of all the crops the year 1920 stands for the agricultural year 1920/21.

Bengal agriculture 1920-1946

1.7 JUTE (*cont.*)

| Year | Official acreage (in '000s) | Output ('000 tons) | Revised acreage (in '000s) | Revised output ('000 tons) | Yield per acre (in lbs) |
|------|--------------------------------|-----------------------|-------------------------------|-------------------------------|----------------------------|
| 1937 | 30 | 95 | 35 | 110 | 1268 |
| 1938 | 31 | 96 | 36 | 111 | 1233 |
| 1939 | 24 | 66 | 28 | 77 | 1098 |
| 1940 | 122 | 364 | 89 | 265 | 1191 |
| 1941 | 38 | 110 | 41 | 119 | 1159 |
| 1942 | 56 | 156 | 61 | 168 | 1112 |
| 1943 | 46 | 120 | 50 | 130 | 1043 |
| 1944 | 40 | 125 | 43 | 135 | 1261 |
| 1945 | 48 | 155 | 52 | 167 | 1295 |

Note: As shown in chapter 1, Table 1.12, the margin of error was not the same during the whole period. Therefore, the figures in the revised series are calculated by using separate Revision Factors for the five quinquennial periods. Data on acreage and output were often revised by the Director of Agriculture and published in the Calcutta Gazette. These figures have been used in preparing the official series. Output figures are in thousand bales.

2.2 DESCRIPTION OF LAND USE: REVISED SERIES (*cont.*)

(All figures are in 'ooo acres)

| Year | Net cropped area | Double cropped area | Current fallow | Cultivable waste |
|------|------------------|---------------------|----------------|------------------|
| 1922 | 7418 | 304 | 116 | 854 |
| 1923 | 7054 | 356 | 132 | 959 |
| 1924 | 6843 | 304 | 170 | 1005 |
| 1925 | 6916 | 181 | 187 | 924 |
| 1926 | 6751 | 170 | 211 | 902 |
| 1927 | 5979 | 148 | 258 | 1032 |
| 1928 | 7025 | 950 | 201 | 858 |
| 1929 | 7198 | 285 | 203 | 883 |
| 1930 | 7107 | 632 | 221 | 881 |
| 1931 | 7017 | 536 | 199 | 935 |
| 1932 | 6969 | 478 | 185 | 1021 |
| 1933 | 7110 | 339 | 177 | 1018 |
| 1934 | 6073 | 260 | 217 | 1177 |
| 1935 | 5594 | 207 | 256 | 1217 |
| 1936 | 6921 | 378 | 199 | 930 |
| 1937 | 6742 | 410 | 224 | 904 |
| 1938 | 6328 | 552 | 292 | 1013 |
| 1939 | 6516 | 596 | 250 | 1089 |
| 1940 | 5859 | 503 | 325 | 891 |
| 1941 | 6221 | 442 | 196 | 838 |
| 1942 | 6150 | 443 | 241 | 950 |
| 1943 | 6089 | 445 | 202 | 950 |
| 1944 | 6031 | 447 | 266 | 1007 |
| 1945 | 5115 | 384 | 277 | 1017 |

Note: The same Revision Factor is used to revise the official figures for the period up to 1941/42. Separate Revision Factors are used for the later years.

3.1 DATA ON PHYSICAL CAPITAL

(All figures in '000s)

| Year | Occupied houses | Draught animals | Ploughs |
|-------------------|-----------------|-----------------|---------|
| <i>All-Bengal</i> | | | |
| 1920 | 8461 | 18351 | 4458 |
| 1926 | 8704 | 18937 | 4689 |
| 1930 | 8904 | 18703 | 4599 |

Bundwan

| | | | |
|------|------|------|-----|
| 1920 | 1515 | 3460 | 741 |
| 1926 | 1551 | 3747 | 788 |
| 1930 | 1582 | 3700 | 787 |
| 1935 | 1676 | 3503 | 702 |
| 1940 | 1792 | 3316 | 626 |
| 1945 | 1915 | 3198 | 649 |

Note: As explained in chapter 5, no cattle census was held in 1935. Therefore, figures for this year on livestock labour, and agricultural implements have been interpolated on the basis of the growth rate between 1930 and 1940. Livestock labour includes bullocks, cows and buffaloes (both male and female).

Bengal agriculture 1920-1946

4.I DATA ON PRIMARY CREDIT SOCIETIES

(All figures are in '000s)

| Year | Societies | Members | Working capital (Rs) | Loans granted (Rs) | Loans paid (Rs) | Loans due (Rs) |
